INDEX

A. Acronyms----------------------------------------------- vi
B. General definitions ---------------------------------- viii
C. Reference ranges for biochemical assessments-------- ix
D. Executive summary ---------------------------------- xi

CHAPTER 1: Introduction -------------------------------- 1
1.1 Introduction ----------------------------------------- 1
1.2 Context of malnutrition ----------------------------- 1
1.3 Need for a National Nutrition Survey --------------- 5
1.4 Survey duration ------------------------------------- 6

CHAPTER 2: Survey Design and Methods--------------------- 7
2.1 Survey Objectives ------------------------------------ 7
2.2 Methodology ----------------------------------------- 7
2.3 Sample size its allocation --------------------------- 7
2.3.1 Sample size estimation for household survey and biochemical assessment ----------- 7
2.3.2 Sampling frame and design ------------------------- 9
2.3.3 Sample selection procedure ------------------------ 10
2.3.4 Target population --------------------------------- 10
2.3.5 Description of questionnaire ----------------------- 10
2.3.6 Description of qualitative research --------------- 11
2.3.7 Biochemical analysis ------------------------------- 11
2.3.8 FATA specific data ------------------------------- 11
2.3.9 Project pre implementation steps ------------------- 12
2.3.10 Plan of operation, training and monitoring ------ 14
2.3.11 Data management, transfer and analysis ----------- 14
2.3.12 Ethical approval and confidentiality ------------- 15

RESULTS OF THE NATIONAL NUTRITION SURVEY -------------- 16

CHAPTER 3: Background and Household Characteristics------ 17
3.1 Completion of data collection ------------------------ 17
3.1.1 Blood and urine specimen ------------------------- 18
3.2 Background and household characteristics ----------- 18
3.3 Formal education – head of household and mothers--- 18
3.4 Occupation – head of household --------------------- 18
3.5 Nature of dwelling by type of floor, roof and walls -- 19
3.6 Type of cooking fuel ------------------------------- 20

CHAPTER 4: Food Insecurity in Pakistan--------------------- 21
4.1 Food secure ----------------------------------------- 21
4.2 Food insecure without hunger ------------------------ 21
4.3 Food insecure with hunger (moderate) --------------- 22
4.4 Food insecure with hunger (severe) ------------------ 22

CHAPTER 5: Maternal Health and Nutrition------------------ 23
5.1: Basic data – age, education and marital status of mothers 23
5.1.1 Age distribution ------------------------------- 23
5.1.2 Marital status and current pregnancy status ------ 23
5.2: Reproductive history and antenatal care ------------- 23

General Definitions

**Body mass index (BMI):** Statistical measure of weight scaled according to height, determined by dividing a person’s weight by the square of their height in metric units. For adults, a BMI of less than 18.5 typically indicates under nutrition, while a BMI of more than 40 indicates morbid obesity.

**Complementary feeding:** This is the period starting when breast milk alone is no longer sufficient to meet the nutritional requirements of infants. Other foods and liquids are needed to complement breast milk at this stage. This transition from exclusive breastfeeding to family foods typically covers the period from 6 months to 18-24 months of age.

**Exclusive breastfeeding:** The practice of only feeding breast milk to an infant with no supplementation of any kind (e.g. no water, juice, food, or non-human milk). Exclusive breastfeeding has been shown to provide improved protection against many diseases. According to the World Health Organization, on a population basis, exclusive breastfeeding for six months is the optimal way of feeding infants. Thereafter infants should receive complementary foods with continued breastfeeding up to two years of age or beyond.

**Malnutrition:** Various forms of poor nutrition leading to both underweight and overweight conditions caused by a complex array of issues, including dietary inadequacy, infections, and socio-cultural factors. Malnutrition can lead to wasting and stunting, micronutrient deficiencies, as well as diabetes and other diseases.

**Micronutrients:** Nutrients needed for life in miniscule amounts. These substances enable the body to produce enzymes, hormones and other substances essential for proper growth and development. Micronutrients are used to improve nutrition through processes such as bio fortification and supplementation.

**Stunting:** Failure to reach linear growth potential because of inadequate nutrition or poor health, also defined as a chronic restriction of growth in height indicated by low height-for-age. Stunting is usually a reliable indicator of long-term under nutrition among young children.

**Supplementation:** Process of supplying nutrients – in forms such as bars, capsules, and powders – those missing or not consumed in a person’s diet. Typical supplements include vitamin A, iron, and zinc.

**Under-nutrition:** According to the 2008 Lancet series on maternal and child under nutrition, under nutrition includes a wide array of effects including intrauterine growth restriction resulting in low birth weight, underweight, stunting, wasting and less visible micronutrient deficiencies. Under nutrition is caused by poor dietary intake that may not provide sufficient nutrients, and/or by common infectious diseases such as diarrhoea. These conditions are most significant during the first two years of life.
**Underweight:** This indicates a person has a low weight for their age and implies stunting or wasting. The rate of underweight children is the percentage of children who have low weight for their age.

**Wasting:** Acute weight loss indicated by a low weight for height ratio. Wasting is usually a result of acute starvation or severe disease. Often more chronic during the first two years of life, wasting is part of a pattern of under nutrition.

Executive Summary

The Pakistan’s National Nutrition Survey 2011 was conducted by Aga Khan University’s Division of Women and Child Health, Pakistan’s Ministry of Health and UNICEF. The major objective of NNS 2011 was to assess the population nutritional status (especially of women and children and/or other target groups), and key micronutrient indicators in comparison with the last survey in 2001.

The findings of NNS 2011 provide relevant information for planning, implementation and monitoring appropriate population based interventions in Pakistan. Population groups surveyed included: pre-school children (0–59 months old), school aged children (6–12 years old), women of childbearing age (15–49 years old), and elderly persons (50 years and above). This was the first time a National Nutrition Survey provided provincial specificity with representative population based samples. However, it does not offer district level estimates. A two stage stratified sampling design was adopted and an overall sample size of 30,000 households was selected and calculated on the basis of major nutrition indicators used in the 2001 NNS. These included: 1. stunting in children and 2. Anaemia among women of reproductive age (WRA) and in children. In all, 27,963 households interviewed; 24,421 blood samples were taken (women 12,282; children 12,139); and 2,917 urine samples were collected from women (1,460) and children 6-12 years (1,457) for urinary iodine assessments.

The NNS 2011 covered all provinces: Gilgit Baltistan (GB), Balochistan, Khyber Pakhtunkhaw (KP), Sindh, Punjab, Azad Jammu and Kashmir (AJK) and the Federally Administered Tribal Areas (FATA). This included 1,500 enumeration blocks (EBs)/villages and 30,000 households, with a 49% urban and 51% rural distribution. Renewed listing of all households in each enumeration block was conducted and twenty households were selected randomly using a computer automated selection process. Twenty-two survey teams conducted field activities included data collection, biochemical samples and physical examination across Pakistan.

Results from the 2011 National Nutrition Survey (NNS) indicated little change over the last decade in terms of core maternal and childhood nutrition indicators. With regard to micronutrient deficiencies, while iodine status had improved nationally, vitamin A status had deteriorated and there had been little or no improvement in other areas linked to micronutrient deficiencies. The ratio of males to females was approximately 50.4% to 49.6% across Pakistan. A total of 45.7% of household heads were illiterate and 38.7% were workers or laborers. 15.5% of the population was unemployed – with higher rates in the urban population (18.9% urban unemployment, 14.0% rural unemployment). Using a standard questionnaire, the NNS 2011 indicated that 58.1% of households were food insecure nationally.
Overall, in Pakistan, 51.9% mothers were having normal weight, 14.1% thin and 33.9% overweight while thin mothers were highest (16.4%) in rural areas compare to urban (9.0%) and overweight mothers were higher (48.4%) in urban areas compare to rural (27.4%). Among the regions and provinces the ratio of overweight mothers was highest (38.2%) in KP and thin mothers were highest (20.6%) in Sindh.

Night blindness prevalence reported by women who were pregnant at the time of this survey was 12.7% while night blindness prevalence reported by women during their last pregnancy was 15.6%. Approximately 42.8% of the population reported awareness of the importance of iodine whereas 64.2% reported awareness about the benefits of iodized salt. Only 39.8% reported using iodized salt whereas kit-testing results confirmed use at 69.1%. This is a significant improvement over the 2001 NNS result of 17%. Overall knowledge of the importance of vitamin A in Pakistan was 24.0%. Knowledge about other micronutrient deficiencies was very low with significant rural and urban differences.

Widespread micronutrient deficiencies were found in women. For example, the survey discovered the following micronutrient deficiency levels in pregnant women: Anaemia 51.0%, iron deficiency anaemia 37.0%, vitamin A deficiency 46.0%, zinc deficiency 47.6%, vitamin D deficiency 68.9%. The prevalence of micronutrient deficiencies in non-pregnant women were as follows: Anaemia 50.4%, iron deficiency anaemia 26.8%, vitamin A deficiency 42.1%, zinc deficiency 41.3%, and vitamin D deficiency 66.8%. Adequate iodine status was documented at national level and in most of the provinces. Balochistan, AJK and GB were the only provinces that documented inadequate levels (<100 μg/l median iodine excretion) of iodine status.

The proportion of women who were breastfeeding was estimated on the basis of feeding practices in the past 24 hours dietary recall. Data indicated 63.5% of mothers predominantly breastfed children from 0–6 months of age and 77.3% of mothers continued breastfeeding up to 12–15 months.

Anthropometry status has not changed much over the past decade. Among children under 5, 43.7% were stunted in 2011 as compared to 41.6% in the 2001 National Nutrition Survey. 15.1% were wasted compared to 14.3% in 2001 and 31.5% were underweight, which has not changed since 2001 (NNS 2001). The anthropometric indices were relatively better in urban areas.

Micronutrient deficiencies were also widespread in children. Biochemical analyses revealed the prevalence of various micronutrient deficiencies in children <5 years of age: Anaemia 61.9%, iron deficiency 43.8%, vitamin A deficiency 54.0%, zinc deficiency 39.2% and vitamin D deficiency 40.0%.
An illustrative sample of 7,612 elderly persons was examined at their residence during the survey. The data revealed that more than half (53.9%) of the Pakistan’s elderly population did not have normal weight; they were either underweight or overweight. Among them 15.8% were thin, 24.2% overweight and 13.9% obese.

The National Nutrition Survey 2011 indicates that stunting, wasting and micronutrient malnutrition are endemic in Pakistan. These are caused by a combination of dietary deficiencies; poor maternal and child health and nutrition; a high burden of morbidity; and low micronutrient content in the soil, especially iodine and zinc. Most of these micronutrients have profound effects on immunity, growth, and mental development. They may underlie the high burden of morbidity and mortality among women and children in Pakistan. Increasing rates of chronic and acute malnutrition in the country is primarily due to poverty, high illiteracy rates among mothers and food insecurity. Such rates can also be attributed to inherent problems in infant feeding practices and lack of access to the age-appropriate foods.
Chapter 1: Introduction

1.2 Introduction

Pakistan is a federal parliamentary republic consisting of four provinces – Balochistan, Khyber Pakhtunkhaw, Punjab and Sindh – and four federal territories – the capital Islamabad, the Federally Administered Tribal Areas (FATA), Azad-Jammu and Kashmir (AJK) and Gilgit Baltistan (GB). Bordering India, China, Iran and Afghanistan, the country can be divided into the Indus plain in the East, the mountainous area in the North and Northwest and the Balochistan plateau in the West. [1]

Pakistan is the sixth biggest country in the world, with an estimated population of more than 180 million people. It has the second largest Muslim population of any single country after Indonesia. Ranking 141 out of 182 countries in the Human Development Index (HDI), Pakistan is an impoverished and underdeveloped country. Life expectancy at birth stands at 65 years and the adult literacy rate is 49% (male 63%, female 36%).

Pakistan is a disaster-prone country and is exposed to a multitude of natural disasters including earthquakes, floods, storms and droughts [2-6]. The country was under military dictatorship for 33 of its 64-year existence.

The security situation in Pakistan is complex. There are a number of overlapping threats, including the presence of non-state actors targeting government installations and security forces, especially in the areas bordering Afghanistan. [4, 6]

1.2 Context of malnutrition

Estimates suggest that more than 150 million malnourished children around the world are under 5 years of age. It is also well recognized that half of the 12 million deaths among children under 5, or almost 54% of young child mortality in developing countries, can be linked to malnutrition. [8] Studies suggest that malnutrition has a multiplicative effect on the risk of mortality from infectious diseases. [9]

Like other major health issues, malnutrition is a prevalent problem in the South Asian region. Half of the world’s malnourished women and children are found in just three countries: Bangladesh, India and Pakistan. South Asia is the worst affected region and presents what has been termed an “Asian Enigma” due to high rates of low birth weight (LBW), unhygienic conditions, unsatisfactory breastfeeding and weaning practices and the poor status of women. [10]

Malnutrition is a recognized health problem in Pakistan and plays a substantial role in the country’s elevated child morbidity and mortality rates. Due to its correlation with infections, malnutrition in Pakistan currently threatens maternal and child survival, especially in poor and
underdeveloped areas. However, there are concrete solutions, which depend on political will, economic advancement and viable targeted research. [7]

The number of underweight children and women is very high in the South Asian region. About one third of babies are underweight and more than half of women of reproductive age weigh less than 45 kg. [11] It is believed that malnourished adult women have a much higher risk of giving birth to low birth weight infants. Infants born with a low birth weight are at a higher risk of morbidity and mortality in the neonatal period or later infancy, especially in developing countries. [12] The infants who survive are often poorly breastfed and weaned, resulting in stunted and malnourished children. These conditions result in children growing into adults who are less prepared to contribute to society and productivity, thus adding to poverty and unemployment in the country. Low birth weight women also develop into malnourished mothers who give birth to LBW babies and perpetuate this cycle.

Stunting is used as a reliable indicator of growth retardation in developing countries. The stunting rates in Pakistan fell from 47% in 1980 to about 33% in 2000. [13] It is estimated that the most important factors associated with lower prevalence of stunting are the availability of high-energy nutrients, female literacy and gross national product. [16] Challenges linked to these factors are still serious in Pakistan and particularly affect children, young girls and women. [16] Like other developing countries in South Asia, with the exception of Sri Lanka, the situation in Pakistan linked to maternal and child under nutrition is serious. [18] Pakistan’s prevalence of stunting declined from 67% in 1977 to an estimated 40-50% and remained at such levels until the end of the 1990s. However, these rates are still very high when compared to the global average. [19] According to the national survey (1990-94), among the urban middle to lower economic group, the prevalence of stunting was approximately 30-36% and as high as 35-45% in the same economic group in rural areas. [20] The national survey categorized economic status on the basis of material possessions and facilities owned by the household. However, it used different criteria for urban and rural households. Thus, Pakistan’s urban-rural difference may be partially explained by the relatively higher level of education among the urban population as well as their access to basic health services. [21]

Malnourished children begin to fall behind on their regular growth at around six months of age. This is the time when an infant starts receiving complementary foods in addition to breast milk. [22] The divergence from normal growth is linked to a combination of poor nutrition and intra-uterine growth. [23] This problem is aggravated by the burden of morbidity. [24] Poor quality and quantity of complementary foods and inadequate caring practices are the key determinants for this early phase of childhood growth retardation, [25] which can lead to late onset of the childhood growth spurt and subsequent retardation. [26] Growth faltering is linked to a series of occurrences a child suffers, including repeated illnesses, inadequate appetite, insufficient food intake and poor standard care. Many of these children die before their first birthday and those who survive suffer long-term consequences such as weak stature and challenged mental capacity. [27]
Pakistan’s economy is largely dependent on agricultural output. The country's farmers cultivate sufficient amounts of diverse crops to feed most of the population, which makes the degree of malnutrition even more distressing. However, the issue of malnutrition has been a constant challenge in Pakistan for decades. The micronutrient survey in 1976-1977 revealed that 60% of children under 5 were malnourished. Widespread malnutrition in younger infants was further highlighted by a survey of children under 2 years of age. [28] The results of these surveys were confirmed by high rates of early childhood malnutrition from studies conducted in Lahore. [29,30] The National Nutrition Survey that was conducted in 1985-87 further revealed that 48% of children were malnourished and 10% were severely malnourished. The 2001-2002 National Nutrition Survey also showed a dire malnutrition situation in Pakistan. This was the first time a NNS highlighted the true extent and burden of macronutrient and micronutrient malnutrition in the country. [31]

Widespread macronutrient malnutrition coupled with subclinical micronutrient deficiencies prevail in South Asia and have been largely ignored in the region and in Pakistan. “Subclinical deficiency” is micronutrient malnutrition without visible signs of deficiency, also termed as the “hidden hunger”. It is estimated that more than seven million people suffer from clinical forms of these micronutrient deficiencies and another 2 billion from subclinical forms. [32]

Various studies and surveys from Pakistan indicate that subclinical micronutrient deficiencies such as iron-deficiency, zinc deficiency and vitamin A deficiency are widespread among pre-school children and women of reproductive age, particularly pregnant women. [31] A survey conducted with pre-school children in the North West Frontier Province (now Khyber Pakhtunkhwa) revealed that about 50% of the children showed evidence of significant anaemia and zinc deficiency. [33] Data on micronutrient malnutrition are scarce and limited. Only a few studies have been conducted on a local scale and these cannot be relied upon to measure larger scale issues. [34]

To implement successful strategies and sustainable interventions, the direct and indirect causes of Pakistan’s huge malnutrition burden must be identified. The analysis below identifies some of the determinants of malnutrition in Pakistan and the impact these factors have on the status of malnutrition in the country.

More than 30% of Pakistan’s population lives below the poverty line. [35] The Gini coefficient, used to measure economic inequality in a society (using the range of 0 to 1, “0” indicating complete equality and “1” indicating complete inequality), is 0.410 in Pakistan. This shows a very high rate of inequality. The poorest 20% of the population earn 6.2% of the country’s total income and most households in Pakistan spend almost half of their income on food. Poor food availability, poor quality of diet, and limited knowledge about nutritious foods all contribute to a vicious cycle of malnutrition. Political issues, security issues linked to non-state actors and unemployment in the country have amplified this problem. Another important risk factor contributing to malnutrition is a high and repeated burden of infections.
Repeated acute respiratory infections (ARI), diarrhoea and other infections lead to a decrease in dietary intake and nutrient use due to loss of appetite and reduced absorption. [36]

Poor breastfeeding and weaning practices are also common in Pakistan. As a result, infants do not consume adequate calories, proteins and micronutrients. While almost 90% of women breastfeed their children, very few start breastfeeding within one hour of birth and most of them discard colostrum considering it as waste or impure milk that is not suitable for their babies. The rate of exclusive breastfeeding in the first four months is only 16%. The current number of mothers introducing complementary foods at the right time is low and poor food choices commonly result in increased risk of diarrhoea and malnutrition. It is well known that lack of awareness about proper nutrition and feeding practices, coupled with poor food choices, trigger the widespread use of weaning diets with poor micronutrient content and bioavailability. [37]

The fertility rate in Pakistan is very high. On average, Pakistani women give birth 6.8 times in their lives. Approximately only 28% of women between 15 and 49 years of age use contraception. A high fertility rate and lack of birth spacing result in a continuous cycle of pregnancy and lactation. Such a cycle can deplete the body reserves of an already malnourished mother.

The adult literacy rate in 2011 in Pakistan was low, 67% for males and 42% for females. It is believed such low levels of education among women in Pakistan influence their reproductive behaviour. It also makes reproduction related decisions in families and in society at large principally dependent on men’s knowledge and practices. In general, women in Pakistan have very little control over areas of life such as food distribution within household and family planning. [38, 39]

Antenatal care plays a vital role in the wellbeing of mothers and growing children. The care a mother receives during pregnancy and after delivery determines how well she will be able to feed and care for her child. This includes breastfeeding, food preparation, general care, hygiene and home health care. In Pakistan most pregnant mothers are unaware of the importance of antenatal care and have limited access to health facilities. The use of antenatal health care facilities is very low in the country and access has remained static over the years. To make matters worse, in 2011 trained health personnel attended only 39% of births. [40]

The rates of malnutrition in children under 5 determined by the 2001 National Nutrition Survey (NCHS standard) were as follows: wasting 13%, underweight 38% and stunting 37%. In the same survey about 13% of non-pregnant and 16% of pregnant women were reported to be malnourished (BMI<18.5). Similarly high estimates for micronutrient deficiencies shocked both the Pakistani population and the world. In terms of iodine deficiency about 7% of school going children (6 -12 years) had either palpable or visible goitres on clinical examination. Vitamin A deficiency, as measured by serum retinol levels, quoted 6% of mothers and 12.5% of pre-school children to be deficient.
Evaluation for iron deficiency showed 45% prevalence in mothers and 66.5% in children. Caring practices were also recognized as poor in the same survey. Many of these indicators are well above the World Health Organization (WHO) cut off points and warrant putting in place immediate public health measures and programs.

The direct and indirect factors that lead to malnutrition contribute to nearly 35% of all under 5 deaths in Pakistan and affect the future health, socioeconomic development and productive potential of the society. Despite an increase in food availability over the past 20 years there has been little change in the prevalence of malnutrition in the population. This may be related to the cross-sectoral and complex nature of malnutrition, which includes issues related to poverty, intra-household food security and contemporary socio-cultural factors determining dietary patterns in pregnancy and early childhood.

### 1.3 Need for a National Nutrition Survey

National Nutrition Surveys provide an estimate of the severity and geographical scope of nutrition related challenges in a country. They also expose problems closely linked to nutrition issues and identify the most-at-risk groups. Nutrition surveys assess the likely evolution and impact of nutrition levels on the health and nutritional status of the population at large while taking into account secondary information such as food security and food distribution. They also help identify what types of nutrition interventions would be most effective to prevent or minimize the problem in the future. Governments use national surveys when deciding whether or not to establish or expand existing nutrition surveillance and to ensure effectiveness and monitor progress over time. To assess the magnitude of the problem, governments and partners also look at the population size, demographic characteristics of the population and distribution of malnutrition cases therein.

To understand the underlying causes of under nutrition and to plan and implement appropriate interventions and programs to improve the situation, the government and partners must identify the current nutritional status of both the population at large and vulnerable groups, recognize changes in nutritional status over time, and acknowledge the context in which challenges have surfaced. Sources of information that promote a deeper understanding of this context and help identify potential responses include formal nutrition surveys, food security surveys and records of malnutrition cases. Formal nutrition surveys are still the best way to accurately estimate prevalence of malnutrition because they reveal trends in the number of malnutrition cases and identify opportunities for action.

The last National Nutrition Survey was conducted in 2001/2002, almost 15 years after the 1985/1987 National Nutrition Survey. Almost a decade later, the current survey was undertaken with the following goals:

- Establish the current nutrition benchmark and related indicators for gauging progress toward the targets set for the Millennium Development Goals (MDGs);
Establish a benchmark for missing data/indicators, especially since the recent Demography and Health Survey (DHS) did not include anthropometric indicators.

Prioritize the programs and initiatives at the national and provincial level and refine the planning and implementation of initiatives on the basis of identified priorities.

### 1.4 Survey duration

Data collection began in January 2011 and was completed on 30 June 2011. The survey teams underwent five days of extensive training led by senior and experienced staff from The Aga Khan University who had experience conducting similar surveys in Pakistan and also abroad (Sri Lanka and Maldives). Training sessions and refreshers were conducted in Karachi, Faisalabad, Lahore, Rawalpindi, Peshawar, Abbottabad, Quetta and Gawadar.
Chapter 2: Survey Design and Methods

2.1 Survey Objectives

The specific objectives of the National Nutrition Survey 2011 were:

- Assess the population’s nutritional status, especially children under 5, women of reproductive age, adults and elderly on a national and provincially representative sample.
- Collect specific representative data on height, weight and age of children under 5 years of age, women of reproductive age, adults and elderly.
- Collect blood specimens for micronutrient status assessments of children and women of reproductive age – mainly vitamin A, zinc, calcium and vitamin D, and iron.
- Collect urine samples to assess the iodine status of women of reproductive age and children between 6–12 years of age.
- Assess infant and young child feeding and care practices, including breastfeeding, complementary feeding and morbidity of children.

2.2 Methodology

The survey was conducted at national scale through a representative cross-sectional survey at household level. Cross-sectional surveys are useful in providing an overall estimate of prevalence and coverage in a geographic area. The survey used both quantitative and qualitative methods to achieve the objectives. The survey consisted of interviews, measurement of anthropometric indices, collection and testing of biologic specimens. A multi stage cluster methodology was designed so as to provide national and provincial representative data. This survey was conducted in all the four provinces (Sindh, Punjab, Balochistan and NWFP) plus Azad Jammu and Kashmir (AJK), Gilgit Baltistan and Federally Administered Tribal Areas (FATA) as defined by the 1998 population census.

2.3 Sample Size and its Allocation

2.3.1 Sample size estimates for household survey

After considering a variety of characteristics including population distribution and field resources available, a sample size of 30,000 households was calculated as a sufficient number of households to provide representative results. An exercise to compute the sample size based on the prevalence rate of three key variables – wasting in children under 5 years of age, stunting in children under 5 and maternal iron deficiency – was undertaken.

The sample is estimated to have a 95% confidence interval and a 5% margin of error. A 5% non-response rate was also considered. The design effect of 1.6 was used to finalize and fix the overall sample size. The entire sample of 30,000 households (SSUs) was fixed comprising of 1,500 (PSUs) out of which 618 were urban and 882 were rural. As the urban population was more heterogeneous, a larger proportion of the sample size was allocated to urban domain. As KP and Balochistan are smaller provinces, a higher proportion of the sample size was allocated to these two provinces in order to obtain reliable estimates. After fixing the sample size at provincial level, further distribution of sample PSUs into different strata in rural and urban
domains in each province was made proportionately. The distribution of PSUs and SSUs enumerated in the urban and rural domain of the provinces and regions is indicated below:

* Including Islamabad

**A-Biochemical Assessment:** For biochemical analysis prevalence of Anemia in women and children was taken as an indicator for sample size estimation. For 51% prevalence of anemia in women and 29% in children (NNS 2001), with a precision of 2%, design effect of 1.6 and power of 90% the sample size achieved was 8534 for WRA and 7032 for children under five years of age. 15% attrition rate was added to the sample size achieved and the final sample size came to 9836 for WRA and 8100 for children under five years.

For biochemical assessment we selected households where having a pair of mother and under five children, the youngest child (under five) was selected for blood sampling from selected households. The below table describes the sample size and its distribution among the WRA and Children under five years of age in various regions.

**B. Sampling Frame and Design**

**A- Universe of the survey:** The universe for this survey was comprised of all urban and rural areas of all four provinces of Pakistan, the Federally Administered Tribal Areas (FATA), Azad
Jammu Kashmir (AJK) and Gilgit Baltistan (GB) defined as such by the 1998 Population Census, and the subsequent changes made by the provincial governments periodically. The population of the military restricted areas was excluded from the scope of this survey.

**B-Sampling frame:** For National Nutrition Survey in Pakistan the sampling frame of Federal Bureau of Statistics (FBS) was used. The Federal Bureau of Statistics (FBS) has its own sampling frame for all urban and rural areas of Pakistan in the form of enumeration block. Each enumeration block consists of about 200 to 250 households with well-defined boundaries, which are recorded on forms and maps that also include physical features of the area and important landmarks.

**B.1: Urban areas:** In urban areas each enumeration block has been classified into low, middle or high income groups depending on what income group the majority of the households located in that particular enumeration block belonged to. This information was then used to formulate sub-stratification. This sampling frame covers all urban areas of Pakistan due to rapid growth in these areas; the frame is regularly updated every 5 to 7 years. It was entirely updated in 2004. There are 26,753 enumeration blocks in all urban areas of the country.

**B.2: Rural areas:** The Enumeration blocks in In rural areas consists of mouzas, dehs and villages. A mouza, deh or village can be defined as the smallest “revenue estate” and FBS has used these as rural Enumeration blocks. The rural sampling frame is comprised of 50,572 mouzas/dehs/villages and has been used to draw the sample for this survey.

**C-Role of Federal Bureau of Statistics in Sample design and Frame:** FBS was one of the main collaborators in the implementation of National Nutrition Survey; FBS provided the sample size estimation, sample design and the sampling frame providing the provincial representativeness. The Sampling frame for NNS was comprised of 1500 PSU (618 Urban and 882 Rural) randomly selected from their main sampling frame. FBS also provided support for the listing of households in each PSU.

**D-Listing of Households (SSU) in each enumeration Block (PSU):** Fresh listing of households was undertaken in all enumeration blocks (PSU) after a comprehensive training of the quantitative survey team. The sketch map of enumeration blocks drafted by the Federal Bureau of Statistics (FBS) in urban areas was used to perform listings. In rural areas, villages were taken as the PSUs, in line with the 1998 Population Census. Large sample villages that have a population of more than 2,000 (according to the 1998 Population Census) were split into hamlets/blocks of equal size. One of these blocks was selected randomly for data collection. Small villages were completely listed. The listing of households was used to select a specified number of households from urban and rural sample areas.

**2.3.3 Sample selection procedure**

**a) Selection of primary sampling units (PSUs)**

Enumeration blocks in urban domain and mouzas/dehs/villages in rural domain were taken as PSUs. In the urban domain, sample PSUs from each ultimate stratum/sub-stratum were selected
using the PPS method of the sampling scheme. In the rural domain, the number of households in the enumeration block from the 2004 Economic Census and the population from the 1998 census for each village/mouza/deh were considered as the measure of size.

b) Selection of secondary sampling units (SSUs)
Households within the sample PSUs were taken as SSUs. Twenty Households from each urban and rural sample PSU were selected with equal probability using a systematic sampling technique with a random start. Complete household lists freshly prepared during the listing activities was used to draw the required SSUs from the list of households.

2.3.4 Target population
The target population included women of reproductive age (15–49 years), children 0–59 months and elderly persons (>50 years).

2.3.5 Description of questionnaire (quantitative)
A structured questionnaire was used to obtain the data. The questionnaire was developed using standard components from previous and recent surveys undertaken nationally and internationally. All the data collection tools were thoroughly assessed by the technical committee established to oversee the NNS 2011. Three iterations of the survey instrument were reviewed and the final version was approved in December 2010. In Section 1 of module “A”, all members of each household were listed by their gender, age, education, occupation and marital status. Besides such information, anthropometry (height, weight and clinical examination for anaemia, jaundice, cyanosis, edema and goitre) was conducted for anyone who was present at the time of the survey. Data corresponding to the name of each member was recorded. Section 2 of module “A” was exclusively designed for obtaining socioeconomic data along with health and hygiene characteristics. Knowledge, attitudes and practices about micronutrients (iron, iodine, and vitamins A, B, C and D) were recorded in the module “B” while module “C” focused on reproductive history, intra-birth interval, antenatal care, night blindness, worm infestation, iron supplementation and morbidities. Additionally, module “C” assessed dietary intake and food practices using a 24-hour dietary recall to determine patterns of eating habits and variety of foods consumed over a longer period of time by WRA. The infant and young child feeding (IYCF) Module “D” was used to capture several indicators including data on birth, newborn weight, resuscitation, breastfeeding initiation, complementary feeding, micronutrients, and 24-hour dietary recall and food practices for the youngest child. A separate Module “E” was developed to determine the health status, immunization, physical examination and lab investigation of children under-5 years of age. The appetite, movement, mobility and morbidities of elderly persons were also investigated in Module “F”. The poverty assessment and food security Module “G” was also completed.
2.3.6 Description of qualitative research
The overall aim was to identify food consumption patterns, nutrition and food behaviour as well as to gain insight into the factors affecting decision-making. These factors include, the connection between diet, disease and health, beliefs about certain foods, dietary practices, food intake patterns, consumption of local versus imported foods, and other factors relating to food choices.

A-Qualitative research sample and target population
In qualitative research, purposive sampling is the dominant strategy and purposive sample size is often determined on the basis of theoretical saturation (FHI, 2005). A total of 40 focus group discussions and 16 in-depth interviews were conducted. Participants were identified and selected through the community recruiters at their living sites.

2.3.7 Biochemical analysis
Biochemical assessment for micronutrient deficiencies was performed on children under 5 years of age and women of reproductive age. Children between 6–12 years of age and WRA were also assessed for urinary iodine. Details of the biochemical test that were done for NNS are shown in table below.

Table 2.3: Description of biochemical analysis/tests

2.3.8 FATA Specific Data
The sample size for the National Nutrition Survey was calculated to be representative at regional level. However, in FATA higher refusal rate (about 32%) was recorded. Therefore data from FATA lost its regional specificity considering this fact we have presented the data of FATA in the report at National level but not at regional level. We presented FATA specific data in the annexes along with other regions but have recommend caution in its use and interpretations. Furthermore, the refusal rate for collection of blood samples was even higher. Considering this fact the biochemical assessments of FATA have not been presented.
2.3.9 Project pre-implementation steps

Before launching the field activities the following steps were undertaken:

</tr>
</tbody>
</table>

A-Identification and recruitment of field staff: Advertisements (in-house and in the national daily newspapers) were placed and candidates were shortlisted and interviewed in Karachi, Faisalabad, Rawalpindi, Peshawar and Quetta.

B-Survey teams Initially 15 survey teams were established and more teams inducted as the survey progressed to keep the momentum and to meet the time target. At one point, 22 teams were simultaneously operating in different parts of the country. Each team consisted of 1 field supervisor, 1 team leader, 4–5 data collectors, 3 registered nurses (with 1 phlebotomist), 2 logistic assistants and 2 community facilitators. Separate teams consisting of moderators and facilitators, observers, note-takers and community recruiters were also established.

C-Staff profile: The staff team included a national survey coordinator, a senior survey coordinator and survey coordinators. All the team supervisors were senior medical doctors and lead social scientists with over ten years of experience in nutrition related surveys nationally and internationally. The team included experienced female team leaders who were trained in social
sciences. They helped gain access to households to ensure the quality and validity of data. All data collectors were at least university graduates supported by logistics assistants and local community facilitators.

**D. Separate teams for mapping and listing:** Each team consisted of a FBS representative and a logistic assistant and were supported by local community facilitators as they visited each EB/village prior to data collection for demarcation of the EB/village as per FBS maps. During this exercise, all structures and households were listed and allotted a unique ID (NNS 1, 2, 3 for structures and HH 1, 2, 3 for households). Additionally, basic data including that of children under 5 years of age, the household head, women of reproductive age and elderly persons above 50 years of age were obtained. From each of the listed HHs in the EB, 20 HHs were randomly selected through a computerized process using Microsoft Excel.

**E. Training:** Training sessions and refreshers were conducted in Karachi, Faisalabad, Lahore, Peshawar, Abbottabad, Quetta and Gawadar. These sessions took place over a period of five days and were carried out by staff from the department of paediatrics and child health of Aga Khan University who had prior experience in similar surveys. Some of the details of the training agenda are shown in Table 2.5.

**F-Piloting/pre-testing:** A pre-test was undertaken to pilot the questionnaire and to identify and solve unforeseen problems before actual data collection. The objectives of the pre-test were to improve the language of the questionnaire; establish the order of questions; check accuracy and adequacy of the questionnaire instructions such as “skip” and “go to”; clarify the instructions to the interviewers; eliminate unnecessary questions and add necessary ones; endeavour to lessen discomfort, harm, or embarrassment to the respondent; improve translation of technical terms; and estimate the time needed to conduct an interview.
Both the “participating” and “undeclared” pre-tests were undertaken. Participating pre-tests were done in the classroom among the interviewers themselves while undeclared pre-tests were done in the field without informing respondents that it was a pre-test. About 100–150 respondents with reasonably similar characteristics from the survey population were interviewed in different parts of Karachi. The questionnaire was then revised and finalized on the basis of the pre-test results and direct observations by survey supervisors. The survey coordinators also closely monitored the pre-testing.

**G-Coding scheme for assigning processing:** A seven-digit coding scheme was developed in order to provide processing codes to primary sampling units [i.e. enumeration blocks/villages (PSUs)] and secondary sampling units [i.e. households (SSUs)].

### 2.3.10. Plan of operation, training and monitoring

In order to ensure timely completion of the survey, effective tools were developed for periodic field activity checks. A one step forward strategy was developed instead of the conventional approaches of monitoring. Additionally, internal monitoring survey stakeholders including Federal and Provincial Nutrition Wings, the Ministry of Health, the Government of Pakistan and UNICEF were proactively engaged in the training sessions as well as in monitoring and evaluating the progress of the survey activities. Besides this, independent and experienced monitors were also engaged.

**A-Data Collection:** On the day of survey the team identified each selected household using the listing being recently done by the listing team and proper informed consent was taken before the data collection. A total of twenty households from each enumeration areas were selected and data collection on the structured instrument was done. The team leader ensured the completion of data collection and quality of data in each cluster. For Biochemical assessment every third household was selected for Biochemical assessment. A Mother and her youngest child under five years were selected for blood draw. Blood samples were collected by trained phlebotomists ensuring safe injection practice. The blood samples were sent to Nutrition Research Lab of Aga Khan University through the national network of Clinical labs of Aga Khan University. Cold chain was ensured during the transportation of the samples.

### 2.3.11 Data management, transfer and analysis

The filled-in questionnaires were first desk-edited at the field sites for completeness and checked for major errors by the team leaders. Once this was complete, the questionnaires were sent through a courier service to Aga Khan University’s Data Management Unit (DMU) in Karachi, where a full time desk was established to receive the survey questionnaires, maintain log registers and check for completeness. Where there was inconsistency or missing responses, the editors flagged the errors/omissions and consulted the team leaders for clarification. Before data entry, all questionnaires were coded for open-ended responses.

**A-Software for data entry and analysis:** Visual Fox Pro was used for designing the databases, data entry software and procedures for data quality assurance. Range and consistency checks as well as skip patterns were built in the data entry program to minimize entry of erroneous data.
Special arrangements were made to enforce referential integrity of the database so that all data tables were related to each other. Analysis of data was undertaken using SPSS version 18.

**B-Data entry and quality checks:** Two pass verification or double data entry was carried out for each filled-in questionnaire to minimize keypunch errors. An error check program was also incorporated into the data entry system to ensure quality of data. Data entry started after one week of data collection following clearance by the survey coordinator and requisite data quality assurance.

**C-Data Analysis:** Data analysis SPSS version 18 was used and data was analysed. Statistical Analysis was performed after the availability of clean and quality data. Each file was converted from Fox Pro into SPSS files so that they could be read into SPSS for further analysis. Descriptive statistics for the subjects was obtained and frequency tables were generated to ascertain the information on various variables. Data was analysed using univariate method. Analysis was done to ascertain and establish an association with the malnutrition of children.

WHO Anthro (version 3.2.2, January 2011) was used for anthropometric analysis. However, ENA-SMART software was used to check the day-to-day consistency of anthropometric data, which helped to address measurement errors at the initial stages of data collection. We used height for age Z scores, weight for height Z scores and weight for age Z score to assess the level of malnutrition. Ranges of -6 to +6, -5 to +5 and -6 to +5 Z scores were used to assess HAZ, WHZ and WAZ respectively while we flagged the values of < -6 and > +6, < -5 and > +5 and < -6 and > +5 in HAZ, WHZ and WAZ respectively. The flagged values were excluded from the data analysis to avoid measurement bias. We also done weighted analysis to limit the variability among enumeration blocks and region, pre assigned weights from FBS were used to conduct this analysis

**2.3.11. Ethical approval and confidentiality**
The survey design, sampling strategy and analytical plan were reviewed and approved by the Aga Khan University’s Ethics Review Committee as well as by the National Bioethics Committee (NBC) of the Government of Pakistan. Confidentiality of all collected data was assigned high priority during each stage of data handling. All the names and personal information regarding any individual were kept confidential and data sets were kept anonymous for analysis. Only senior staff had access to the data. All data files have been protected by passwords and serum and blood samples were duly secured, as per standard procedures of the institution.
Results of the
National Nutrition Survey 2011
Chapter 3: Background and Household Characteristics

3.1 Completion of data collection

The required sample size for data collection was 30,000 households. The survey teams were able to approach the required number of households, however, 6.8% of the sampled households refused to participate in the survey. A total of 27,963 households consented to participate in the survey and interviews were conducted successfully. The refusal rate varied widely between regions – the lowest being in AJK at 1.3% and the highest being FATA\(^1\) at 32.8%. This was possibly related to the prevalent insurgency, security issues and accessibility in the FATA region. A verbal consent was obtained from participating households prior to the interview for permission to collect information and anthropometric measurements through a pre-printed questionnaire. For blood draws, urine samples collection and clinical examination a written consent was obtained. The NNS 2011 coverage and population density maps for comparison of sample distribution and population conglomeration are featured below:

![Fig 3.1 Population density](image1)

![Fig 3.2 National Nutrition Survey coverage](image2)

Sample size coverage by provinces and regions is listed in the next table.

\(^1\)Data from FATA are not representative due to high non-response rate.
3.1.1 Blood and urine specimen
Overall 24,421 blood samples (12,282 women and 12,139 children) were collected across Pakistan. The survey teams also collected 2,900 urine samples from women (1,460) and children 6-12 years (1,457) for biochemical assessments.

3.2 Background and household characteristics
The total population counted in the surveyed households was 187,095. Males slightly outnumbered females (approximately 50.4% of the population were males and 49.6% females). The gender breakdown was 101.6 males to 100 females, which differed from the last census conducted in 1998 that found 108.5 males for every 100 females. This is, however, similar to the 2006 Pakistan Demographic and Health Survey statistics, which found 102 males for every 100 females. However, in AJK it was 95.7 males per 100 females. The average household size was 6.6, which is similar to what was found in the 1998 census.

3.3 Formal education – head of household and mothers
In the NNS 2011, 45.7% of the household heads were illiterate. The proportion of illiterate heads of household was lowest in AJK at 27.3%, whereas the proportion was highest in Balochistan at 58.2%. Female literacy in Pakistan has been a challenge for many decades.

The results of the NNS 2011 showed that the proportion of illiterate mothers was 59.3% and the proportion was almost double in rural areas than in urban areas (36.6% urban and 69.4% rural). Only 10.5% of mothers completed their 10 years of schooling and 9.0% managed to complete their studies beyond grade 10. Data from the survey further revealed that about 10.9% of mothers from rural areas received education 9th grade and above while in urban areas 38.8% achieved the same.

Fig 3.3: Formal education of mothers of children under five years of age.

* Data from FATA are not representative due to high non-response rate and must be interpreted with caution.
3.4 Occupation – head of household
The NNS 2011 data showed that 53.6% of household heads were labourers, workers or farmers. Of these, 35.9% belonged to the urban population and 61.6% to the rural population. In comparison to the previous findings in the NNS 2001, 16.6% of household heads belonged to the labour/worker/farmer groups. Government and private service employees were the second largest group of those in employment (16.4%). The figures showed that the proportion of unemployed heads of households had doubled since 2001 (7.7% in 2001 compared to 15.5% in 2011).

3.5 Nature of dwelling by type of floor, roof and walls
The survey found that a large proportion of people living in urban and rural areas lacked basic civic necessities. The NNS 2011 data show that 64.2% of families were residing in houses that were constructed using bricks and concrete, which was an increase from the NNS 2001 findings (50%). The facilities available differed significantly between urban and rural areas, with less houses constructed with bricks and concrete in the rural areas (53.7%) than in the urban areas (86.9%). In 2011, across Pakistan 20.7% of household walls were made only with bricks and 55.9% houses had cement or tiled floors. 40.8% of houses had mud/sand floors – 10.2% in urban areas and 54.9% in rural areas. Rural households were more likely than urban households to have sand or mud floors, while urban households were more likely than rural households to have floors made with cement.

3.6 Type of fuel used for cooking

Over the last decade the use of firewood has decreased. At the time the NNS 2011 was being carried out, around 57.9% of the households in Pakistan were still using firewood as the prime source of cooking fuel while the use of firewood was reported to be 66.7% in the NNS 2001. At 35.8%, natural gas was found to be the second main source of cooking fuel. This was available in 83.3% of households in urban areas. Use of animal dung as fuel was observed to have reduced significantly in all parts of Pakistan. Only 6.1% were using animal dung during the NNS 2011 as compared to 14.6% in the NNS 2001. The use of kerosene oil also reduced substantially from 3.3% to 0.2%.

Fig 3.6: Source of fuel for cooking
Chapter 4: Food Insecurity in Pakistan

According to the FAO Publication, *The State of Food Insecurity 2001*, “Food security [is] a situation that exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life”\(^2\) No single indicator can capture the full range of food insecurity and hunger and the most reliable methods require periods of observation and household food inventories. Instead, most commonly household levels of food insecurity or hunger are determined by obtaining standardized information on a variety of specific conditions, experiences and behaviours that serve as indicators of the varying degrees of severity. While developing the module and data collection data were collected using standard internationally validated food security question; these included:

- Anxiety that household food budget or food supply may be insufficient to meet basic needs.
- The experience of running out of food, without money to obtain more.
- Perceptions by the respondent that the food eaten by household members was inadequate in quality or quantity.
- Adjustments to normal food use, substituting fewer and cheaper foods than usual.
- Instances of reduced food intake by adults in the household, or consequences of reduced intake such as the physical sensation of hunger or loss of weight.
- Instances of reduced food intake or consequences of reduced intake for children in the household.

The following steps were followed to analyse the food security data considering the guide to measuring household food security as a standard:

- Converting the survey responses collected using the core-module questionnaire into the data set needed for applying the measurement model;
- Applying the model to the data to determine the food security status level of each household;
- Determining the severity level of the condition experienced in those households that show evidence of food-insecurity/hunger.

In the NNS 2011 the household food security was determined on the basis of four categories: food secure, food insecure without hunger, food insecure with hunger (moderate) and food secure with hunger (insecure). Given that the sample was not powered for provincial estimates, we report national averages.

4.1. Food secure

This category include households that show no or minimal evidence of food insecurity.

4.2. Food insecure without hunger

Food insecurity is evident in household members’ concerns about adequacy of the household food supply and in adjustments to household food management, including reduced quality of food and increased unusual coping patterns. Little or no reduction in members’ food intake is reported.

4.3. **Food insecure with hunger (moderate)**
Food intake for adults in the household has been reduced to an extent that implies that adults have repeatedly experienced the physical sensation of hunger. In most (but not all) food-insecure households with children, such reductions are not observed at this stage for children.

4.4. **Food insecure with hunger (severe)**
At this level, all households with children have reduced the children’s food intake to an extent indicating that the children have experienced hunger. For some other households with children, this already has occurred at an earlier stage of severity. Adults in households with and without children have repeatedly experienced more extensive reductions in food intake.

The results revealed that 41.9% of households were food secure at the national level. 28.4% were food insecure without hunger, 19.8% were food insecure with moderate hunger and 9.8% were food insecure with severe hunger. Rural households were more food insecure (60.6%) as compared to urban households (52.4%).

The food security situation showed no signs of improvement since the last food insecurity assessment conducted by the United Nations in Pakistan\(^3\), which revealed that 51% of the population was food insecure. The situation has, in fact, deteriorated further. This will have serious implications on the nutrition, growth and health of the Pakistani population.

\(^3\) WFP (2009). Food insecurity in Pakistan.
Chapter 5: Maternal Health and Nutrition

During the National Nutrition Survey 2011, detailed data were collected on basic nutritional indicators including dietary intake, reproductive history, anthropometry, clinical and biochemical micronutrient deficiencies and on knowledge and practices linked to micronutrients.

5.1: Basic data – age and marital status of mothers

5.1.1 Age distribution

The survey revealed that about 63.7% of mothers were between 20–34 years of age, 28.2% were between 25–29 years and 23.9% were between 30–34 years. The data revealed no major differences between urban and rural age group distribution.

5.1.2 Marital status and current pregnancy status

Only 1.3% of mothers were either separated or widowed (2.0% urban; 1.0% rural), the rest of them were currently living with their husbands. Among all married women (24694), 10.0% women were pregnant. Provincial results showed variations; number of currently pregnant women was the highest in Sindh (11.9%) followed by Punjab 11.2%, AJK 9.1%, GB 7.3%, KP 6.0% and Balochistan 5.1%.

5.2: Reproductive history and antenatal care

5.2.1 Reproductive history

29.7% of women surveyed had been pregnant 1 to 2 times, 46.6% had been pregnant 3 to 5 times and 23.7% had been pregnant 6 or more times. The data did not find any major difference in the number of pregnancies between urban and rural areas but provincial variation was observed. Further data regarding outcome of the last pregnancy showed that 93.4% of pregnancies resulted in live births, whereas 5.7% ended as miscarriages and 0.8% in stillbirths.

5.2.2 Antenatal care

Antenatal care during last pregnancy: Seeking antenatal care during pregnancy is of great importance as it identifies risk factors. Unfortunately, there has been no improvement in the percentage of women seeking ANC since 2006-07. The PDHS 2006-07 data showed that 65.3% of pregnant women sought care during their last pregnancy while the NNS 2011 results found 62.0% sought ANC. The data revealed a clear difference of ANC seeking behaviour patterns when comparing women living in urban areas, where 81.4% sought ANC, and rural areas, where 53.7% sought ANC. Provincial data revealed that women who sought care during their last pregnancy in Punjab was 66.5%, Sindh 61.6%, KP 55.7%, Balochistan 47.1%, AJK 80.8% and GB 80.0%.
B-Choice of care provider: The selection of a qualified and skilled health care provider ensures quality care during pregnancy. In Pakistan, the percentage of women seeking care from skilled care providers has not significantly improved. The survey showed that in 2011 58.9% of mothers received ANC from a skilled provider. Of those who sought care from a skilled provider, 49.5% received care from a qualified doctor, 7.1% from a nurse and 2.3% from a Lady Health Visitors. The percentage of women who sought care from skilled birth attendants varied by province: Punjab 63.6%, Sindh 59.8%, KP 50.9%, Balochistan 42.6%, AJK 79.6% and GB 77%.

C-Micronutrient Supplementation during pregnancy: Data on women’s micronutrient supplementation during their last pregnancy were also collected. 24.4% of pregnant women consumed iron (33.2% in urban areas and 20.4% in rural areas); 25.3% consumed folic acid (35.7% in urban areas and 20.7% in rural areas); 3.9% consumed micronutrients; and 35.6% consumed calcium. The details of the nutrition supplements consumed during last pregnancy are illustrated below in figure 5.3.
5.3: Knowledge of micronutrients and micronutrient rich foods

Micronutrient deficiencies are an important public health problem in Pakistan. In the NNS 2011, questions were asked to determine respondents’ level of knowledge about micronutrients, micronutrient rich foods and the impact of deficiencies (the education level of the respondents was taken into account).

5.3.1 Knowledge of micronutrients

To obtain information on micronutrient knowledge, survey respondents were asked simple questions such as, “Have you ever heard about (name of micronutrient)?” to determine if they knew what “foods contain (name of micronutrient)” and the “impact on health if deficient.”
The survey found that knowledge about micronutrients was generally low and varied greatly between urban and rural areas. Only 24.8% of mothers had knowledge about iron across Pakistan – 42.0% in urban and 17.0% in rural areas. Only 6.1% of mothers had knowledge about zinc – 12.8% in urban areas and 3.1% in rural areas. 24.0% mothers had knowledge about vitamin A – 41.6% in urban areas and 16.0% in rural areas. 20.8% of mothers had knowledge about vitamin D – 38.0% urban areas and 13.0% in rural areas. 19.3% of mothers had knowledge about vitamin B complex – 34.4% in urban areas and 12.5% in rural areas. Finally, 42.8% of mothers in Pakistan had knowledge about iodine – 61.6% in urban areas and 34.2% in rural areas.

### 5.3.2 Knowledge of vitamin rich foods

Pregnant women are considered to be a nutritionally vulnerable segment of the population due to their greater need for nutritious foods during pregnancy. Marginal nutrient intake increases the risk of nutritional deficiencies during pregnancy. For this reason, it is concerning that across Pakistan only 24.8% of mothers had heard about iron and half of them did not know which foods contain iron. However, among those who knew, 36.5% mentioned that green leafy vegetables contained iron while 20.1% mentioned meat. Mothers also had poor knowledge about health problems caused by zinc deficiency. Overall, 73.3% of mothers did not know about foods that contain zinc. Only 7.4% mentioned meat and meat products while 2.3% mentioned watermelon seeds as a source of zinc. The majority of mothers (58.4%) in Pakistan did not know which foods contain vitamin A and just a small proportion had knowledge about vitamin A rich foods. The majority of mothers (64.4%) also did not know about Vitamin D rich foods in Pakistan. Only 4.8% mentioned eggs, 9.3% mentioned meat and liver, and 3.7% mentioned sunlight as a source. Approximately 69.6% of mothers were not aware about the vitamin B complex rich foods in Pakistan. 13.4% of women mentioned that they thought fruits contained it and 11.9% mentioned green leafy vegetables were vitamin B complex rich foods.

The national iodine deficiency disorder control program was launched in 1994 to promote use of iodized salt. Nevertheless, across Pakistan mothers had relatively poor knowledge about health problems caused by iodine deficiency. The NNS 2011 survey findings revealed 66.9% of the respondents mentioned iodized salt as the major source of iodine, while just 2.4% were aware of other iodine rich foods like fish and seafood.

### 5.3.3 Knowledge about iodized salt and its usage

Overall, 64.2% of mothers said they were aware of iodized salt. Knowledge of iodized salt was higher (83.0%) in urban areas than in rural areas (55.6%). The respondents from AJK (82.0%), Gilgit Baltistan (79.5%) and Punjab (71.4%) had excellent awareness as compared to other provinces.

The reported use of iodized salt for cooking was 39.8% across Pakistan. A considerable provincial/regional variation was found between Gilgit Baltistan (94.8%), AJK (71.6%) and Punjab (36.1%). The reported use of iodized salt was higher (46.5%) in urban areas than in rural areas (35.2%).
Rapid iodized salt test kits were used in the survey to assess iodine content in salt used in households. The kit can test salt with drops of stabilized starch based solution, which causes a chemical reaction leading to colour change. The salt sample was taken on a teaspoon, and, after shaking the reagent (test solution) bottle well, a drop of the test solution was poured on the salt. The salt turned light blue to dark violet depending on the iodine content of the salt. To assess the iodine content, the colour of the salt is compared to that on a chart (0, 15, 25, 50 parts per million, ppm). The cut-off proportion of 15 PPM and above was considered as adequately iodized salt using the WHO/UNICEF reference indicators for the monitoring of iodized salt.

Fig 5.5: Level of Iodine content in salt

According to the test, the proportion of households using iodized salt in Pakistan was 69.1%. This was higher in urban areas (72.4%) than in rural areas (67.6%). The provinces with the greatest proportion of households using iodized salt were AJK (87.9%) and Gilgit Baltistan (84.9%). The provinces with the lowest rates of usage were Balochistan (40.8%) and Sindh (51.8%).

5 4: Clinical examination

During the NNS 2011, clinical examination of mothers was also performed. Trained nurses conducted this examination. This was a direct assessment of micronutrient deficiencies on the basis of clinical signs and symptoms. The mothers were examined for anaemia, edema, jaundice, goitre and bitot’s spots. Each of these conditions represents a micronutrient deficiency. The survey revealed that overall, 26.1% mothers had pallor – 20.5% in urban areas and 28.6% in rural areas. The prevalence of clinical anaemia (pallor) amongst the provinces were as follows: 28.0% in Punjab, 33.7% in Sindh, 11.0% in KP, 20.2% in Balochistan, 35.9% in AJK and 16.0% in Gilgit Baltistan. The prevalence of edema was 1.6% with no significant variance among provinces except for Gilgit Baltistan where it was 4.1%. Bitot’s spot was found in 0.4% of mothers, with no urban/rural variance. When assessed by province, Balochistan had the highest prevalence of Bitot’s spot (2.8%).
The prevalence of clinical anaemia found in the NNS 2001 was 48.7%. The NNS 2011 revealed a reduction to 26.1%. Similar trends were found for edema, jaundice, visible goitre and bitot’s spot.

**Fig 5.6: Clinical examination of mothers (comparison between NNS 2001-02 and NNS 2011)**

**5.5: Anthropometry**

Data were collected from non-pregnant women of reproductive age (15-49 years old), both married and unmarried, to calculate Body Mass Indices. The BMI were divided into four categories: underweight had a BMI of <18.5, normal had a BMI of 18.5–24.99, overweight had a BMI of 25–29.9 and obese had a BMI of >=30.

The data showed that 18.0% of women had low BMI and were underweight (14.4% from urban areas and 19.7% from rural areas) and about 53.1% had normal BMI (46.0% from urban areas and 56.6% from rural areas). 19.4% of women of reproductive age were overweight and 9.5% of WRAs were obese (15.7% from urban areas compared to 6.5% from rural areas).

**Figure 5.7: Body Mass Index**
5. 6: Micronutrient deficiency

5.6.1. Urinary iodine excretion of mother

In the NNS 2011, urine samples from mothers were collected to assess their urinary iodine excretion. Urinary Iodine excretion is the most appropriate indicator of iodine deficiency in large populations. Adequate iodine nutrition is considered to pertain when the median urinary iodine concentration is 100–199 μg/l.

The median urinary excretion of mothers indicates adequate levels of iodine status at national level, in both urban and rural area, and in most of the provinces (as indicated in the figure below). Balochistan, AJK and Gilgit Baltistan showed <100 μg/l urinary excretion, which indicates that the iodine intake in the population is insufficient.

![Fig 5.8: Median urinary iodine excretion in mothers](image)

5.6.2: Night blindness among mothers

12.7% of women surveyed had experienced night blindness during their previous pregnancy and 15.6% had experienced night blindness during their current pregnancy. Among provinces of Pakistan, women in Sindh had the highest reported rates of night blindness during their last pregnancy (21.3%) followed by AJK, Balochistan, Punjab, KP and Gilgit Baltistan. Among those women who reported night blindness during their current pregnancy, women in Sindh (22.7%) had the highest rates followed by AJK, Balochistan, Punjab, KP and Gilgit Baltistan.

When comparing this survey with the NNS 2001, night blindness rates during previous pregnancies had gone up (12.7% in the NNS 2011 compared to 7.8% in the NNS 2001). Similar trends were seen in urban and rural areas. The night blindness rates during current pregnancies had also increased (in the NNS 2011 they were 15.6%, while in the NNS 2001 they were 9.9%).
Biochemical analysis

Blood specimens were collected to assess the biochemical status of micronutrients. These specimens were assessed for hemoglobin, ferritin, vitamin A, zinc, calcium and vitamin D levels. The results are as follows:

5.7.1 Anaemia (haemoglobin levels)

Haemoglobin levels of both pregnant and non-pregnant women were checked during the NNS 2011. 50.4% of non-pregnant women were found to be suffering from anaemia (49.3% in urban areas and 50.9% in rural areas). Provincial data revealed that 62.0% in Sindh were suffering from anaemia, followed by Balochistan (48.9%), Punjab (48.6%), AJK (41.0%), KP (35.6%) and Gilgit Baltistan (23.3%). Similar trends were observed for pregnant women.

When the NNS 2011 data for anaemia in pregnant and non-pregnant mothers was compared with that of the NNS 2001, it was found that the prevalence of anaemia in non-pregnant women had worsened in 2011 (28.4% in NNS 2001 compared to 50.4% in the NNS 2011). Similar trends were observed for pregnant women.
5.7.2 Ferritin concentration
26.8% of non-pregnant women had low ferritin levels (26.8% in urban areas and 26.6% in rural areas). When the data was disaggregated by province, Sindh had the highest proportion of women with low ferritin levels (31.5%), followed by Punjab, AJK, Balochistan, Gilgit Baltistan and KP. Among pregnant women, 37.0% had low ferritin levels at national level whereas it was highest in GB (45.7%) followed by Punjab, Balochistan, Sindh, AJK and KP.

5.7.3. Vitamin A deficiency
Retinol levels were tested in women (pregnant and non-pregnant) to determine vitamin A deficiency. Vitamin A deficiency among all married women was prevalent at 42.5% (35.7% in urban areas and 45.4% in rural areas). Provincial variance showed vitamin A deficiency at the following levels in all married women: highest in KP 66.4% followed by Balochistan 54.9%, Punjab 41.8%, GB 39.1%, and Sindh 37.1%. Among the non-pregnant women, vitamin A deficiency was prevalent at 42.1% (34.9% in urban areas and 45.1 in rural areas). Provincial variance showed that VAD remained highest in KP 65.7% followed by 54.5% in Balochistan, 41.5% in Punjab, 38.7% in GB, 35.4% in Sindh and 13.7% in AJK. Among the pregnant women, vitamin A deficiency was prevalent at 46.0% (41.5% in urban areas and 47.8 in rural areas).
Provincial variance showed that VAD remained highest in KP 76.2% followed by 60.7 in Balochistan, 46.7% in Sindh, 44.1% in GB, 43.7% in Punjab and 32.2% in AJK.

**Fig 5.13: Vitamin A deficiency (pregnant women)**

Comparison of Vitamin A Deficiency among all women NNS 2011 vs. NNS 2001: Vitamin A deficiency levels found in the NNS 2011 had significantly increased over the NNS 2001 levels (5.9% in 2001 to 42.5% in 2011). Similar trends were seen in urban and rural areas.

**Fig 5.14: Comparison of vitamin A deficiencies among non-pregnant women (urban/rural)**

5.7.4 Zinc deficiency

Serum zinc levels were determined in women. The serum analysis of non-pregnant women revealed that 41.3% of women were zinc deficient (38.2% in urban areas and 42.7% in rural areas). Women’s serum zinc levels by province were as follows in 2011: Punjab 40.2%, Sindh 38.5%, KP 48.3%, Balochistan 43.7%, AJK 64.8% and Gilgit Baltistan 63.7%. The data also showed that 47.6% of pregnant women were zinc deficient across the country. The provincial variance for pregnant women was as follows: Punjab 47.3%, Sindh 44.5%, KP 52.6%, Balochistan 43.6%, AJK 95.8% and Gilgit Baltistan 54.4%.

It was also noted that there has not been any change in the prevalence of zinc deficiency in the last ten years. The prevalence was 41.9% in the NNS 2001 and 41.3% in the NNS 2011.
The NNS 2011 is the first survey in Pakistan assessing Vitamin D deficiency through bio-chemical data at a large scale. Widespread deficiency was found among non-pregnant women – 66.8% were vitamin D deficient (72.5% in urban areas and 64.3% in rural areas). On a provincial level, the prevalence of vitamin D deficiency among non-pregnant women in Punjab was 66.4%, in Sindh 71.2%, in KP 61.0%, in Balochistan 54.6%, in AJK 73.3% and in Gilgit Baltistan 80.9%.

The prevalence of vitamin D deficiency was also tested in pregnant women. 68.9% were determined vitamin D deficient (73.5% in urban areas and 67.2% in rural areas). Provincial data revealed vitamin D deficiency among pregnant women in Punjab was 71.1%, in Sindh 66.9%, in KP 63.8%, in Balochistan 43.6%, in AJK 73.4% and in Gilgit Baltistan 76.1%.
5.7.5 Calcium Status:
The NNS 2011 calculated calcium levels for the first time on such a large population of women (non-pregnant and pregnant). The calculated calcium levels were not adjusted for serum albumin. The data revealed that 52.1% of non-pregnant women had hypocalcaemia. Provincial data also showed that 51.7% of non-pregnant women had hypocalcaemia in Punjab, 74.0% in KP, 63.1% in Balochistan, 8.2% in AJK and 44.5% in GB.

Data on pregnant women showed that 58.9% had hypocalcaemia. The levels of calcium in pregnant women at the provincial level showed that 63.2% of pregnant women in Punjab, 50.3% in Sindh, 67.6% in KP, 67.4% in Balochistan, 13.3% in AJK and 71.3% in GB had hypocalcaemia.
6.1: Nutrition status of children

6.1.1 Children 0 – 59 months
The percentage of households with children aged 0–59 months was measured in the NNS 2011. 25.6% of households in Pakistan did not have a child in the home that was under 5 while 40.1% had only one child less than 5 years of age. The average number of children living in each household is listed by province and region in the following figure.

Fig 6.1: Households with children under 5 years of age

* Data from FATA are not representative due to high non-response rate and must be interpreted with caution.

6.1.2 Anthropometry (children under 5 years of age)
Anthropometric measurement of all children <5 who were present at household at the time of visit was undertaken. Results showed that in Pakistan 43.7% of children were stunted. In rural areas stunting in children was higher (46.3 %) than in urban areas (36.9%). The wasting rate was 15.1% and the proportion of wasted children was lower in urban areas (12.7%) than in rural areas (16.1%). About 31.5% of the children were underweight, with higher rates in rural areas (33.3%). The indicators of malnutrition appeared to be worse in rural areas than in urban areas across country.

Fig 6.2: Prevalence of malnutrition in Pakistan (children under 5 years of age)
6.1.3 Stunting (children under 5 years of age)
Severe stunting in children showed an alarming situation (21.9%) across Pakistan. It was higher in rural areas (24.0%) than in urban areas (16.4%).

Fig 6.3: National stunting rates for children under 5 years of age

6.1.4 Wasting (children under 5 years of age)
Overall wasting rates were 5.8% for severe wasting and 9.3% for moderate wasting. The proportion of wasted children was higher in rural areas than in urban areas. In urban areas 4.7% of children under 5 years of age suffered from severe wasting while 8.0% were affected by moderate wasting. In rural areas severe wasting reached 6.3% and moderate wasting was 9.8%.

Fig 6.4: National wasting rates (children under 5 years of age)

6.1.5 Underweight (children under 5 years of age)
Across Pakistan, 11.6% of children were severely underweight while 19.9% were moderately underweight. No significant difference was found between rural and urban areas.
6.1.6: Education of mothers and its association with nutritional status of children
It is evident that the employment status and education level of a mother is directly associated with the nutritional status of her children. The findings of the NNS 2011 revealed that a mother’s education level is closely associated with children’s stunting, wasting and underweight status. Malnutrition in children was lower for those whose mothers had a higher education status.

6.1.7 Malnutrition trends in children under 5 years of age – comparison of SAARC countries
Of the South Asia Association of Regional Cooperation (SAARC) countries, Pakistan has the second highest stunting rate (43.7%). It follows Afghanistan, a country that faces extreme social, political and economic complexities. Nepal and India have similar stunting rates (43%). Bhutan has considerably better nutrition indicators than Pakistan.
Pakistan and Sri Lanka have the third highest wasting rates in the region and Afghanistan has better rates than both.

Pakistan had lower rates of underweight children than half of the other SAARC countries.
6.2: Biochemical assessment

Biochemical assessments are one of the established methods used to study the micronutrient status of a given population. Biochemical assessments are much more accurate and precise than most other forms of testing because many micronutrient deficiencies do not produce signs or symptoms until they are quite severe. For this reason, mild micronutrient deficiencies can only be diagnosed using biochemical indicators. Commonly used biochemical assessments include the haemoglobin estimation for anaemia, serum retinol levels for vitamin A deficiency, serum zinc levels for zinc deficiency, and urinary iodine levels for urinary iodine excretion.

6.2.1 Anaemia

At the national level, 61.9% of children were found to be anaemic (Hb level <11.00gm/dL) (severe deficiency 5.0% and moderate deficiency 56.9%). Regional differences in the prevalence of anaemia were substantial, ranging from 41.0% in Gilgit Baltistan to 72.5% in Sindh. Prevalence of severe anaemia was comparatively higher in rural areas (5.5%) than in urban (3.6%).

Fig 6.10: Anaemia in children under 5 years of age

![Bar chart showing the prevalence of anaemia in children under 5 years of age across different regions in Pakistan.]

Fig 6.11: Trends of prevalence of anaemia in children under 5 years of age

![Bar chart showing the trends of prevalence of anaemia in children under 5 years of age across different years in Pakistan.]

6.2.2 Iron deficiency (low ferritin concentration)
High levels of iron deficiency (low ferritin concentration) were observed in 43.8% of children across Pakistan. Provincial differences in prevalence of low ferritin levels varied ranging from 26.4% in KP to 48.6% in Punjab. Comparatively high prevalence was noted in urban areas (46.1%) as compared to rural areas (42.9%).

Figure 6.12: Iron deficiency among children

6.2.3 Vitamin A deficiency in children (under 5 years)
During the NNS 2011, vitamin A deficiency was assessed among children. The data showed that overall 54.0% of children in Pakistan were vitamin A deficient. 20.9% were severely deficient and 33.1% were moderately deficient.

Fig 6.13: Vitamin A deficiency
6.2.4 Zinc deficiency

The survey revealed that overall prevalence of zinc deficiency among children in Pakistan was 39.2% (39.3% urban and 39.1% rural). Provincial data showed zinc deficiency at 38.4% in Punjab, 38.6% in Sindh, 45.4% in KP, 39.5% in Balochistan, 47.2% in AJK and 32.6% in Gilgit Baltistan.

Fig 6.15: Zinc deficiency in children (0–5 years)

When zinc deficiency data from the NNS 2011 was compared with that of NNS 2001, there was a slight change in the proportion of zinc deficient children as measured by serum zinc concentrations.
6.2.5 Vitamin D deficiency

The prevalence of vitamin D deficiency among children at national level was 40.0%. A high prevalence of vitamin D deficiency (45.9%) was noted in urban areas. Substantial variations were noted at the provincial level, ranging from 28.9% in KP to 43.4% in Balochistan.

6.2.6 Urinary iodine excretion in children 6-12 years

The main indicator of iodine status in the population is measured by median urinary iodine concentration in a population of children aged 6–12 years. Adequate iodine nutrition is considered to pertain when the median urinary iodine concentration is 100–199 μg/l. Generally, the median urinary excretion of children aged between 6-12 years found in the 2011 survey indicated adequate levels of iodine status at national level, both urban and rural, and in all of the provinces except AJK and GB.
6.2.7 Clinical examination of children under 5 years of age
During the NNS 2011, trained nurses performed clinical examinations of children. The children were examined for anaemia, edema, jaundice, goitre and bitot’s spot. The survey revealed that overall 22.8% of the children had pallor. Provincial variations were found in the prevalence of clinical anaemia ranging from 31.7% in AJK to 3.4% in KP. The prevalence of edema was 0.4% with no significant variance between provinces except for Gilgit Baltistan, where not a single case was found. Bitot’s spot was present in 0.2% of the children.

6.3: Child morbidity
Apart from neonatal disorders, diarrhoea and pneumonia are the other major causes of death in children under 5 years of age worldwide. In the NNS 2011, mothers of children under 5 were asked if the children had symptoms associated with acute respiratory illness (cough/flu, pneumonia, severe pneumonia and diarrhoea) on the day of the interview or two weeks preceding the survey.
6.3.1 Prevalence of acute respiratory infections

ARI is a common cause of morbidity and death among children under 5 years of age. Pneumonia is characterized by difficult or rapid breathing. Severe pneumonia is defined as difficult or rapid breathing and chest in-drawing.

According to mothers of children, 4.9% of children had pneumonia on the day of the interview. However upon observation by the community nurse, 5.4% children had signs consistent with pneumonia. The survey findings revealed that either by observation or reported by mother, the ARI (cough/flu, pneumonia and severe pneumonia) were more prevalent in urban areas than in rural areas across Pakistan. Severe pneumonia symptoms were reported in 1.4% of children and the observed proportion was 1.0%.

6.3.2 Prevalence of diarrhoea

Diarrhoea is also a major cause of mortality among children. Childhood diarrhoea has been a serious health problem in Pakistan. Both its prevention, through improved water and sanitation, and management through oral rehydration salts (ORS) and zinc are on the top of the government’s priority list. The prevalence of diarrhoea was determined using the WHO definition. The mother was asked to report whether her child had diarrhoea on the day of the interview or two weeks preceding the survey.

Fig 6.20: Reported Prevalence of diarrhoea

![Graph showing reported prevalence of diarrhoea](image)

*Data from FATA are not representative due to high non-response rate and must be interpreted with caution.*

Approximately 12.0% of children were reported to be suffering from diarrhoea at the time of the visit and 22.3% had diarrhoea during the previous two weeks. The prevalence of diarrhoea (current and over the previous two weeks) was similar between urban and rural areas.

Current diarrhoea prevalence was highest in Gilgit Baltistan (19.2%) and Punjab (15.6%). Similarly, prevalence of diarrhoea during previous weeks was highest in Punjab (28.5%), Gilgit Baltistan (28.5%), AJK (26.2%) and Sindh (23.4%).
Chapter 7: Infant and Young Child Feeding Practices

Infant and young child feeding (IYCF) practices directly affect the nutritional status of children under two years of age and impact overall child survival. Improving infant and young child feeding practices in Pakistan for children 0–23 months of age is critical to guaranteeing them better nutrition, health and development. **Breastfeeding practices:** In the NNS 2011, the mothers of the children <24 months of age were queried on exclusive breastfeeding (no intake other than breast milk, including water). The reported frequencies at the national level were 20.9% at 4 months of age and 12.9% at 6 months of age respectively. The corresponding predominant breastfeeding data from 24 hours recall of mothers with children under 6 months of age reflected 69.8% and 63.5% at 4 months and 6 months across Pakistan respectively.

**Fig 7.1:** Exclusive breastfeeding of children 0-23 months (reported by mothers)

![Figure 7.1: Exclusive breastfeeding of children 0-23 months (reported by mothers)](image)

*Data from FATA are not representative due to high non-response rate and must be interpreted with caution.*

**Fig 7.2:** Predominant breastfeeding of children 0-6 months (24 Hours dietary recall)

![Figure 7.2: Predominant breastfeeding of children 0-6 months (24 Hours dietary recall)](image)

*Data from FATA are not representative due to high non-response rate and must be interpreted with caution.*
Predominant breastfeeding practices were assessed using the past 24 hour dietary recall of 0-6 months old children. The data showed that 69.8% of mothers were predominantly breastfeeding their children who were under 4 months and 63.5% under 6 months. Predominant Breastfeeding practices were higher in rural areas (66.4%) than in urban areas (57.5%).

**Fig 7.3: Initiation of breastfeeding in less than one hour of birth**

![Graph showing breastfeeding initiation within 1 hour by region]

* Data from FATA are not representative due to high non-response rate and must be interpreted with caution.

NNS 2011 data revealed that 40.5% of mothers had initiated breastfeeding within one hour of birth. The percentage was greater in rural areas (41.4%) than in urban areas (38.4%). The early initiation of breastfeeding was highest in KP 74.3% followed by Balochistan 63.4% and Gilgit Baltistan 61.8%. Trends observed in Punjab (28.1%), Sindh (50.5 %) and AJK (38.3 %) differed.

**Fig 7.4: Continued breastfeeding practices**

![Graph showing continued breastfeeding by region]

* Data from FATA are not representative due to high non-response rate and must be interpreted with caution.
The data showed that in Pakistan 77.3% mothers continued breastfeeding to children up to 12-15 months. Continued breastfeeding practices were higher in rural areas (79.6%) than in urban areas (72.3%). Provincial and regional differences in the rates of continued breastfeeding practices were substantial, ranging from 72.3% in the Balochistan to 91.9% in the Gilgit Baltistan.

**Fig 7.5: Introduction of Semi-Solid (6-8 months)**

* Data from FATA are not representative due to high non-response rate and must be interpreted with caution.

More than half (51.3%) of the mothers interviewed across Pakistan reported they had started giving semisolid foods to their children at 6–8 months. The proportion was higher (68.4%) in urban areas than in rural areas (44.7%). KP (35.3%) and AJK (35.7%) had lower trends than other provinces.

**Fig 7.6: Minimum dietary diversity (6-23 months)**

* Data from FATA are not representative due to high non-response rate and must be interpreted with caution.
Minimum dietary diversity is estimated as the proportion of children 6–23.9 months of age who received foods of 4 or more food groups out of a total number of 7 food groups defined. The NNS 2011 findings revealed that only 3.0% of the children received a diet that meets the minimum standards of dietary diversity. Children in urban areas were more likely to receive a minimum dietary diversity than those in rural areas (5.6% compared to 1.9%). AJK (6.9%) ranked highest in minimum dietary diversity amongst the provinces.

Fig 7.7: Minimum meal frequency (6-23 months)

Minimal meal frequency is estimated as the minimum number of times solid, semi-solid or soft foods (including milk for children who are not breastfed) are given to breastfed and non-breastfed children who are 6-23.9 months of age. “Minimum is defined as 2 times for breastfed infants 6-8.9 months, 3 times for breastfed children 9-23.9 months and 4 times for non-breastfed children 6-23.9 months.” Overall, 56.4% of mothers provided food to their children at an acceptable meal frequency. The minimum meal frequency practice was higher in urban areas (65.4%) than in rural areas (52.4%). About half of all mothers practiced minimal meal frequency in all provinces.

Fig 7.8: Minimum acceptable diet (6-23 months)

* Data from FATA are not representative due to high non-response rate and must be interpreted with caution.

---

4 Indicators for assessing infant and young child feeding practices: conclusions of a consensus meeting held 6–8 November 2007 in Washington D.C., for acceptable diet of young child indicators.
A minimum acceptable diet is a composite indicator of the adequacy of complementary feeding practices. It is the proportion of children 6–23 months of age who received a minimum acceptable diet (apart from breast milk). Across Pakistan only 7.3% of children received a minimum acceptable diet. Similar trends were observed in all provinces except AJK.

**Fig 7.9: Age appropriate breastfeeding (0-23 months)**

![Age appropriate breastfeeding (0-23 months)](image)

*Data from FATA are not representative due to high non-response rate and must be interpreted with caution.*

Age-appropriate breastfeeding was defined as the proportion of children 0–23 months of age who were appropriately breastfed. The proportion of age-appropriately breastfed children was 63.6% in Pakistan. Similar trends were recorded both in urban and rural areas. All provinces showed similar trends with the highest being in Gilgit Baltistan (75.3%).
Chapter 8: Food Intake and Practices

8.1: Methodologies adopted for Food Intake and Practices

Diet is usually described in terms of its nutrient content however the use of specific foods groups can also describe diet. Three of the most common methods used for assessing dietary intake; are food frequency questionnaires, food records and 24-hours dietary recalls. In the NNS 2011, Food Frequency Questionnaire was used to assess the past dietary intake and 24-hour Dietary Recall for the current dietary intake.

8.1.1: Methodology for 24 Hour Recall

An open ended semi quantitative 24-hours dietary recall questionnaire was used to estimate the consumption of various food groups intake. The respondent (mother herself and for her child 0 – 23 months) was asked to report all of the food, beverages and/or supplements that she and her child has consumed during the past 24 hours.

The interview was structured with specific probes to help the mother remember all of the foods eaten. Probing was done in collecting details on different foods and also for in recovering foods that are forgotten (e.g., butter on toast) or in retrieving eating occasions not originally reported by the mother such as snacks or tea breaks.

Standard utensils (Cup, plates, spoons, glass, etc.) were given to the specially trained Data Collectors to measure the actual quantity eaten on 7 points in time during the past 24-hours (after wakeup, breakfast, in-between breakfast and lunch, lunch, in-between lunch and dinner, dinner and after dinner before go to bed).

8.1.2: Methodology for Food Frequency Questionnaire

The food frequency questionnaire was administered to ascertain the information on the frequency of food consumption and nutrients. The purpose of this questionnaire was to know the frequency of food items usually consumed. The respondent (mother herself and for her child 0 – 23 months) was asked to report listed food items in the table. Food frequency per day, per week and per month was estimated.

8.2: Pattern of Food Consumption among Children 0 – 23 month

The data of food consumption were analyzed on the basis of 24-hours dietary recall. Data showed that the pattern of food consumption in 0–23 months by different food groups in Pakistan was: breast milk 80.9%, followed by grains, roots and tubers 58.2% and dairy products (milk, yogurt, cheese, etc.) 48.2%. Breast milk feeding was higher (82.6%) in rural and lower (77.0%) in urban areas however the consumption of other food groups (grains, roots and tubers, legumes and nuts, dairy products (milk, yogurt, cheese), flesh foods (meat, fish, poultry and liver/organ meats), eggs, vitamin-A rich fruits and vegetables & other fruits and vegetables was higher in urban and lower in rural areas. In provincial and regional comparison breastfeeding was highest (92.2%) in Gilgit Baltistan and lowest (73.9%) in Balochistan. Grains, roots and tubers were consumed at the lowest in KP (41.7%) and highest (58.2) in AJK while dairy products were also lowest (41.7%) in KP and but highest (65.1) in Sindh. Details are given in the following table:
Table 8.1: Proportion of children below 2 years consumed food items of the listed food groups (based on 24 hour recall)

8.3: Frequency of Daily Intake of Food Groups (Children 0 – 23 months)

The data showed that average daily intake of breast milk by children 0 – 23 months in Pakistan was 7.37 times on an average (Urban 7.01 - Rural 7.53) while it was the highest (10) in Sindh and the lowest (5.94) in Gilgit-Baltistan. All over Pakistan, the average daily intake of dairy products (milk, yogurt, and cheese) was 1.49 times per day and grains, roots and tubers 1.27 while the lowest intake (0.03) was of both food groups of legumes and nuts and vitamin A rich fruits and vegetables.

8.4: Frequency of Daily Intake of Food Groups among Children by their Age Group

In Pakistan, average daily intake of different foods showed the logical trends in different age groups among children of 0 – 23 months i.e. the higher the age group lowers the feeding of breast milk. The average intake of breast milk was 10.4 times on an average in children <6 months, 8.31 times in children 6 – 11 months and 5.11 times in children 12 – 23 months while on the other hand average of semi-solid foods was lower in children <6 month and gradually increase in higher age i.e. 6-11 and 12-23 moths.

8.5: Pattern of Food Consumption among Mothers of Children below 2 Years of Age

Across the country irrespective of provinces and regions all mothers eat wheat and rice (>99%) however foods also eaten along with wheat and rice were tuber and roots (29.2%), legumes and nuts (29.8%), dairy products (milk, yogurt, cheese) 41.6%, flesh foods (meat, fish, poultry and liver/organ meats) 30.6%, eggs (10.4%), vitamin -A rich fruits and vegetables (13.5%) and other fruits and vegetables (51.4%).

8.5 Frequency of Daily Intake of Food Groups among Mothers of Children below 2 Years of Age

The average daily intake of grains, tuber and roots by mothers of children all over Pakistan was 3.15 times followed by dairy products (milk, yogurt, cheese, etc.) 1.05 times. On an average, other fruits and vegetables apart from vitamin A rich were eaten by 0.85 time in a day.

Chapter 9: Elderly Persons Health and Nutritional Status

Studies suggest that people's perceptions of their own health generally give a good indication of their mental and physical condition and are predictors of mortality for those who are 50 years of age and above. There are a number of factors that are known to have an impact on the general health of the population. These factors can contribute to an increased risk of diseases such as cardiovascular disease and cancer. Some of the contributing factors include cigarette smoking; excessive alcohol, excessive fat consumption; high blood pressure, high cholesterol levels, limited exercise and being overweight. In the NNS 2011, elderly persons were interviewed to determine their health and nutritional status. In all, 7,612 elderly persons were interviewed at their residence.

Fig 9.1: Age distribution of elderly persons

There were 30.4% male and 69.7% female respondents in this sample because mostly women were at their homes during the day. Approximately 42.4% of the elderly population belonged to the age group between 50–59 years (46.3% urban and 40.6% rural).

9.1 Body Mass Index (Elderly Persons):

In all, 69.7% women and 30.4% men were assessed for BMI. The main reason behind this variation was that the data collection conducted mostly from 10 am to 04 pm and menfolk are usually not available at home during this time slot. The data revealed that more than half (53.9%) of the Pakistan’s elderly population does not have normal weight; they were either underweight or overweight. Among them 15.8% were thin, 24.2% overweight and 13.9% obese. In provinces highest thinness was in Balochistan (19.6%) and lowest in KP (7.5%) while about half (49.7%) of the elderly population were overweight and obese in KP. In Gilgit Baltistan 61.6% elderly population maintained normal weight.

*Data from FATA are not representative due to high non-response rate and must be interpreted with caution.*

About half (49.8%) of the rural elderly population was on normal weight whereas it was only 37.5% in urban areas while thinness was higher (19.3%) in rural and lower (8.1%) in urban. The tendency of overweight was 31.0% in rural areas in comparison of 54.4% in urban areas.
Chapter 10: National Nutrition Survey – Qualitative Findings

INTRODUCTION

We conducted 40 focus group discussions and 16 in depth interviews at different places to cover almost all provinces/regions of Pakistan. Focus group discussions (FGDs) were conducted with mothers having child less than five years of age, male & female elders of the family and lady health workers. In-depth interviews were conducted with male & female health care professionals.

Around 400 participants attended these FGDs & IDIs. The characteristics of participants were presented below;

Data were transcribed and translated directly from native language to English. The validity of the transcripts and translations was checked with back translation.

A- PERCEPTION OF HEALTH AND ILLNESS

The majority of rural mothers had opinion that women lack the freedom to access medical care for themselves and their children unless the household decision maker allows them to do so.

Majority of the participants across the country reported fever, cough, diarrhoea and intestinal worms are ailments of children.

Majority of participants from Baluchistan, rural Sindh and southern Punjab said that we have to collect water from wells located outside the house and store it for our use and there is no proper system of collection and disposal of sewerage in the community/locality. The inability to access
clean water and unsatisfactory sanitary conditions are important contributors to many childhood illnesses. Waterborne diseases and worm infestation are very common amongst those living in rural areas or where there is improper sanitation coverage.

Regarding perceptions about women’s health, the most common criterion appeared to be the amount of physical work that they were able to do.

Majority of participants of group discussions stated that if a woman is not looking pale and performing her routine household work she is considered to be healthy. Rural mother stated “In laws expect to do the same amount of work even during pregnancy”. One participant remarked that “if a woman is fulfilling all her routine work and her cheeks are rosy, we assume she is well and healthy”.

The majority of participant acknowledged that joint pains and swelling, leucorrhoea, backache, lower body pain, high blood pressure and irregular menstruation were major illnesses of women. However many mothers from Upper Sindh and Southern Punjab perceived that they were suffering from health problem due to low or insufficient diet. The majority of participants also stated that they do not have enough food to eat, poor and cannot afford eating as desired, even they cannot afford medical care except some home remedies. Access to a health facility was identified as a specific barrier to availing health services during discussions. Location of health facilities, besides that dependency on male decision makers, transportation cost, long waiting times at the facility etc. were also mentioned by participants as major barriers to access health services. Majority of participants acknowledged that if the illness is not serious then some self-medication is done from the leftover drugs, however a few participants said that we consult the nearby health care provider and the also lady health workers for taking advice. Apart from lady health workers, traditional birth attendants (TBA’s) were also consulted for minor ailments. For instance, in Balochistan, upper Sindh, Azad Jammu Kashmir and Gilgit a mixture comprising of cardamom, ginger and lemon is used for treatment of leucorrhoea. Some mothers of Gilgit Baltistan and Khyber Pakhtunkhaw said that women were only permitted to consult ‘lady’ doctors due to the cultural barriers.

Majority of health professionals interviewed had opinion that most patients didn’t follow doctors’ advice and instructions. Patients were generally didn’t complete the course of treatment regimens and follow up with medical professionals.

**B-DIET DURING PREGNANCY AND LACTATION**

The majority of participants of group discussion across country stated that pregnancy was not considered as a special event and no extra dietary consideration was given to it. Although the medical professionals unanimously said that woman should encourage women to eat healthy and extra food during pregnancy and lactation. Across the regions the majority of participants said that diet was dependent on economic circumstances of family and was not a matter of choice. The majority of participant mothers stated that their usual diet consisted of vegetables and milk. Rice, pulses/lentils was also mentioned as staple food by most of participants. Majority of participants across the country said that they cannot afford to buy meat or chicken. Few
mothers also stated that they took vitamin or mineral tablets during their pregnancies and lactation period. The majority of health professionals interviewed were stated that malnutrition, anemia and hypertension can cause complications during pregnancy and delivery.

C - INFANT AND YOUNG CHILD FEEDING PRACTICES

1- Breast Feeding

Almost all participants across country were aware of the necessity breast milk as first feed of the child after birth. During the discussion most of mothers stated that, breast milk is healthy and prevent from illnesses. The majority of mothers were not aware the timing of initiation of breast milk and had different opinions, ranged from immediately within half an hour of birth to up to three days after birth. “Breastfeeding should be initiated within 24 hours of child birth” (Urban Mother – FGD). “It should be initiated within first 1 and half hour after child birth” (Rural Mother – FGD). Mother from urban Punjab stated “We think that immediate breastfeeding after delivery is essential otherwise child will not suck properly which can result in child ill health”.

Most of the mothers interviewed believed breastfeeding should be continued up to two years of age of child. Continued breastfeeding was perceived by mothers to protect them from breast cancer and their child from infections. This was also confirmed in the KAP survey where more than 75% of the respondents from all the sectors opined that breastfeeding should be continued for up to 2 years.

During the discussions and interviews, participants were knowledgeable and had many opinions regarding the benefits of the breastfeeding. Mothers from rural areas also perceived some economic benefits of breastfeeding. The benefits of breastfeeding mentioned for the child during discussion were that it supplied all necessary nutrients, provide antibodies to illnesses, increases child’s mental development digests easily and protects against diarrhea (9%). Other benefits mentioned by the participants in the FGDs were as follows: baby will be healthy and it is good for child’s growth, vital for mental and physical growth, easy to feed and natural and breast milk is not contaminated so it protects against disease and reduces the chance of infection.

However, there were a few mothers who believed that first milk i.e. colostrum should be discarded to get rid of the sour taste. They thought that colostrum caused abdominal pain. Another negative practice

Although there are no medical/ scientific advantages attributed to pre-lacteal food yet ‘ghutti’ is very much a tradition first feed of child across Pakistan. This fact was confirmed by most of participants of group discussions. Honey was identified by most of participant that was commonly used across the country but variation existed as “Gurr” (Jaggery) in Northern Punjab, clarified butter in Northern Punjab/KP /Gilgit-Baltistan, Fennel-flavoured sherbet (Mixture) in Khyber Pakhtunkhaw were also used as first feed after birth of child. Some mothers from Gilgit Baltistan stated that “Donkey’s milk, which is perceived to prevent epilepsy, was also given to child after birth.

Majority of lady health workers acknowledged during discussions that breast feeding is the common norm in rural communities but women still need to know the proper feeding tech-
Majority of mothers were aware that they should be exclusively breastfeeding up-to 6 months. The vast majority of mothers stated that they practiced exclusive breast feeding during first six months of their child but many of them admitted that they also gave water to the child during this time period, especially after the age of four months. The duration of the exclusive breastfeeding varied from 4 months to 7 months. “Exclusive breastfeeding for five months is sufficient for the child” (Mother – FGD).

The multiple factors were identified as barrier for exclusive breastfeeding as lack of milk production, anxiety, exhaustion, psychosocial issues, delayed initiation of breastfeeding. Others factors included promotion of infant commercial formulas leading to misconception in mothers that it is better feed for their babies.

There were some beliefs related to breastfeeding stated by some mothers from rural Sindh that mothers practice to protect their child from disease or the evil eye. To avoid the evil eye, a child should be breastfed separately from everyone. Being watched by others can affect both mother and child. Specifically, it was thought that a child can get indigestion, stomach ache and/or phlegm, if they were observed breastfeeding. It was also believed that the evil eye could dry breast milk. “Children are not given breast milk outside home after sun set because of devil eyes” (Rural Sindh Mother).

Regarding duration of breast feeding, the participants opined from one to two and half years. Most of mothers from Lower Sindh continued to feed till 1.5 to 2 years and similar responses from other provinces. Few mothers from Khyber Pakhtunkhaw stated that duration of lactation as 2 years for male and 2.5 years for female child.

Majority of mother also said that top milk was also introduced during this time. The range of top milk included formula milk, packed milk as well as fresh cow’s milk largely depending on the participant’s socio economic status. One of the participants stated that “they breastfed their infants due to the poverty and unavailability of formula milk in surrounding of rural areas therefore women or young mothers have no choice other than to breast fed”. The most common reason revealed for stopping breastfeeding was pregnancy, child not sucking and followed by insufficient milk.

2- Complementary Feeding

Majority of Pakistani children between 6-9 months of age had commenced complementary foods. The age for introduction of complementary foods was varies across the Pakistan but majority had initiated complementary feeding at about 6 months of age.

The most commonly mentioned complementary food that was first introduced to the child was semolina, rice, bread, sago, rice and milk dessert (kheer), buttermilk, egg, banana, tea, porridge, chapatti, potato curry, lentils, meat and broth, fish and vegetables. Almost all the mothers stated that the consistency of the first foods was thin and liquidy. In the FGDs and interviews, mothers
mentioned that initial CF’s were simply milk mixed in mashed rice. Vegetables are gradually introduced. Rarely was meat or dairy products given as complimentary foods.

From 12 months onwards many mothers start giving the child the same diet as the adults. If regular family foods were given, then mothers first washed these with water to remove the spices—a practice that could potentially contaminate the food if untreated water was used. Spices were gradually introduced. Formula milk was not introduced at all by mothers whereas others introduced formula milk between first and 12 months of age.

According to the guiding principles of complementary feeding, there are six things that could be considered during the complementary feeding stage: amount/quantity; frequency; density/consistency; quality/diversity; hygiene; and responsive or active feeding. There was a lack of knowledge about these facts among majority of mothers but a larger proportion of urban mothers mentioned the various components of good complementary foods than their rural counterparts.

Very few mothers were aware that the density/consistency of complementary foods is an important component of CF. Few mothers could not mention any aspects of feeding they need to consider when preparing complementary foods. Very few mothers stated that the characteristics of good complementary foods should be ones that are rich in energy, protein and micronutrients but half of mothers opined that good CF should be clean and safe.

Majority of the urban and rural mothers were not aware that the ideal age to commence complementary feeding was at 6 months. Some thought the ideal age to commence complementary feeding was 9 months and few stated that the ideal time was at 4 months of age.

Reasons for early initiation of complementary feeding mentioned by the few who did commence CF before 6 months included employment of mother; perceived insufficiency of the breast milk to meet the needs of infant; infant’s reluctance to take breast milk (urban), maternal illness and early pregnancy; child underweight; family members influence mother to initiate CF (rural); poor sucking by infant and perception that breastfeeding hindered in maintaining mother’s figure (urban and rural).

Delayed initiation of complementary feeding was a more common occurrence in Pakistan. The main reasons of delayed initiation of complementary feeding cited were financial (rural and urban); complementary foods cause allergy (urban); the belief that breast milk was nutritious enough to meet infants needs even beyond 6 months (rural and urban); infant gaining well on exclusive breast milk so why initiate CF.

When asked how mothers can determine if the food they are giving to their child is appropriate, almost half of the mothers mentioned that they would know if their child refuses to eat it. Some mentioned that the child would vomit the food. Mothers also mentioned that signals that indi-
cated to them that their child was ready to commence CF were the infants’ interest in eating food.

When the participants were asked as to who actually fed the child, the majority of mothers responded that herself or sometimes the grandmother or an older sibling. The majority of mothers also stated that they generally fed their children in the living room or veranda.

Majority of women in discussions acknowledged that they washed their hands before preparation of food for their children. When participants were asked regarding hand washing of child before meal very few of them were followed that practice. Majority of mothers acknowledged that they don’t use separate utensils (plate, cup or spoon) to feed their children.

Most of mothers also stated that child left over food was eaten by some other family member. Most of urban mothers pointed out, frequent use of refrigerator for storage of child leftover food.

Majority of health care professional interviewed commented that there was a uniform lack of knowledge about diet and nutrition amongst families, including those belonging to affluent backgrounds. One comment was that “Sometimes we have to tell them to buy Rs.10 worth of rice and lentils instead of spending more money on commercial food”.

D- OTHER DETERMINANTS OF MALNUTRITION

The most of participants of group discussions from both urban and rural areas opined that there was no inequality in distribution of food in terms of proportion and quantity between boys and girls in the family. However a mother of the focus groups was stated that “boys must get more food than girls because they have more responsibilities in future”.

Some participants were said that “the family sat down together at the meal time but that food was served in order of seniority” Mothers from southern Punjab said that. “Feeding the girl child is not a viable deal as she has to go another house after marriage”. Another mother stated that “The male child is an important asset because he will be productive and bring income into the family. He will also be responsible for carrying the name of the family”.

The role of culturally deep rooted food taboos across the provinces also plays its part in affecting health and nutrition. The concept of “Hot” and “Cold” was observed across the country during group discussions. 

Majority of participants across all provinces were able to segregate food into the hot and cold variety. The common perception in all regions was that eggplant, bitter gourd and meat have a ‘hot’ effect. Cold food includes vegetables, raw mango, rice and lentils in Lower Sindh, Zucchini, Okra and Pumpkin in Upper Sindh, spinach, carrot and cucumber in Baluchistan, pumpkin in Southern Punjab, lentils, and dairy products and Apricot extract in Gilgit.

“Hot” foods also included seafood in Lower and Upper Sindh, meat in Upper Sindh, Northern and Southern Punjab and Gilgit Baltistan, okra in Southern Punjab, Azad Jammu Kashmir, green vege-
tables in Southern Punjab, clarified butter and eggs in GB, lentils in GB/Azad Jammu Kashmir and soup, spinach and spices in Azad Jammu Kashmir. Some mothers said that they avoided giving “hot” food to young girls as it would speed up puberty in them.

Some participants from rural areas also highlighted another interesting myth present within society elders that taking medicine in the form of “pill/capsule” during pregnancy is harmful. Some lady health workers in pointed that “we cannot convince the women to take vitamin or iron supplements because they are suspicious that it will harm the baby”, while a women participant stated “even if I take the medicine home my mother in law will not allow me to taking it”.

The most of participants across all regions acknowledged the importance of education for their children. Mother from rural area stated. “We know that by educating our children we can build a better life and secure a future for our children”. The major barriers to education stated by most of participants included cultural biases, economic and access issues. A mother from KP stated that “We want our girls to go to school but there is discouragement from our elders and we are unable to convince them”.

Chapter 11: What Next

A-Implications for interventions and research

The key finding from the NNS 2011 is that very little has changed over the last decade in terms of core maternal and childhood nutrition indicators. The survey does point towards gains in iodine status nationally following the implementation of a universal salt iodization and promotion strategy. However, this is counterbalanced by substantial deterioration in vitamin A status and little to no gains in other areas of micronutrient deficiencies. These are reflective of an insufficient response to the nutrition situation in Pakistan and the lack of coordination in developing and implementing of a coherent nutrition strategy. A draft nutrition strategy was developed in 2003–2004 and was approved by the planning commission. However, its final approval and implementation never took place. Additionally the efforts of the bilateral agencies and the World Bank have not translated into a tangible response. Although the floods of 2010 and 2011 once again highlighted the seriousness of under nutrition in Pakistan, the response was largely reactive with little movement towards a national strategy for addressing under nutrition.

Despite the fact that these aspects of the poor nutritional status of women and children of Pakistan have been known for a long time, and have been the subject of multiple surveys, there is little public awareness at a national level of the importance and impact of nutrition in the social and economic development of society. Several successive governments have failed to recognize the level of importance nutrition has in the health and development of the population. Nutrition has thus remained unrecognized in current social safety nets and income support programs. Given the agrarian nature of the national economy, there has been consistent denial of household food insecurity. This is especially true in the case of girls and women in Pakistan and few effective interventions target them.

There is a widespread perception that malnutrition is closely related to poverty. While the relationship cannot be denied, it is complex and the poverty-nutrition interaction in Pakistan is strongly influenced by the degree and form of female subjugation, which affects the girl child and women alike.

It must also be recognized that nutrition is more than food and poverty is more than mere income or assets. The few nutrition related interventions in Pakistan that have been undertaken over the last fifty years have largely followed the pattern of vertical programs and are largely supported through external aid and grants. These include vitamin A supplementation, wheat flour fortification and promotion of iodized salt use. A huge amount of resources have been invested in therapeutic feeding of malnourished children in the wake of the floods but relatively less in preventive and promotion strategies. Although there have been breastfeeding promotion and support programs at both community and facility level, (through the LHW program and the Baby Friendly Hospital initiative), the comparable rolling out of complementary feeding promotion and education strategies or the provision of fortified nutritious weaning foods has been lacking. Not surprisingly, the net impact of all such interventions has been negligible in
terms of either nutrition awareness or improvement. In addition to planning nutritional interventions, the creation of a demand at a population level for adequate nutrition is pivotal for the success of any initiative. Neither widespread malnutrition nor poor dietary practices amongst Pakistani women and children have been subjects of national awareness or public education campaigns. In addition to well-designed interventions, Pakistan needs a mass campaign for public awareness on the importance and impact of malnutrition on the nation’s health.

There is thus an overwhelming argument for making an investment in adequate nutrition for the families and children of Pakistan, as a means for economic revival and boosting national morale. Although Pakistan has had several national nutrition surveys in the past, none have resulted in a national intervention program aimed at addressing the root causes and effects of malnutrition. To illustrate this, although a food aid initiative has been in place for several years under the management of the World Food Program and Pakistan Bait-ul-Maal, its impact and effectiveness in reaching the most needy has been limited. For any nutrition intervention to succeed, it is imperative that it be part of a community-based intervention targeting some of the underlying determinants of malnutrition such as household food security, culturally acceptable food choices, as well as communal decision making for promotion of health and nutrition. These interventions must be firmly grounded in the principles of equity, community participation and ownership, while retaining scientific validity.

The alarming findings from the NNS 2011 – indicating vast inequities in indicators – suggest the urgent need for action and the implementation of a range of interventions for women and children. These include the review of existing programs for quality, such as the vitamin A supplementation program, micronutrient fortification strategies and interventions to address food insecurity. Some pilot projects are underway and additional strategies need to be identified that may help soil zinc repletion interventions with national staples.

As the NNS 2011 indicates, stunting, wasting and micronutrient malnutrition is endemic in Pakistan, and reflects a combination of dietary deficiency; poor maternal and child health and nutrition; a high burden of morbidity; and low micronutrient content of the soil, especially for iodine and zinc. Most of these micronutrients have profound effects on immunity, growth and mental development, and may underlie the high burden of morbidity and mortality among women and children in Pakistan.

So what can be done? Nutrition is an area that necessitates a multi-sectoral approach for interventions. Some of the activities that could help address the issues are within the domain of the health sector while others merit broad sustained support and collaboration of other sectors and partners. For coherence, the foundation of the nutrition strategic plan has been laid down under the overall framework of the Pakistan Poverty Reduction Strategy (PRSP). This document defines the roles and activities that the production and social sectors must assume in order to attain the overall objective of socio economic improvement, including a better quality of life.
The strategic territories where multi-sectoral support and coordination is imminently required are institutionalization of nutrition; food safety and regulatory mechanisms; food fortification; and social change communication. The interventions that fall within the umbrella of the health sector are in the areas of maternal, infant, child, adolescent, adult and elderly persons’ nutrition. Collaboration between all partners is essentially required for improving the nutritional status of the target population with synergy. Given the devolution of health to the provinces, it will become even more imperative to develop a concerted and coherent national policy. The need for a central coordination and oversight mechanism to support provinces, especially those with limited capacity is imperative given the wide disparities highlighted by the NNS 2011. Among the various functions, this unit could also be required to form linkages that create social safety nets, address agricultural and food safety, and enforce food industry regulation.

Effective “social change communication” is a vital component of most successful programs and products created to reach and change behaviours in the society at large. Innovative and effective communication strategies can target misconceptions and educate the population about nutrition interventions and practices while still being sensitive to cultural ideas and practices. The integration of child nutrition with child survival becomes imperative. Similarly, given the high rates of maternal and child morbidity and mortality in Pakistan, nutrition interventions should be closely integrated with strategies for maternal, newborn and child health. The role of addressing some of the basic determinants of maternal and child under nutrition in Pakistan cannot be stressed enough. These include addressing issues of maternal education, empowerment and basic rights. It can be argued that some of the maximum gains for maternal education can be achieved by reducing high fertility rates, addressing inappropriate child spacing, and delaying the age of marriage (avoiding early marriages).

We would also like to underscore emerging areas of focus that have hitherto been ignored. One of these is the role of adolescent health and nutrition. As defined by WHO the age group ranging from 10-19 years is considered adolescent and is estimated at about 19% of the total population. Adolescent nutrition has so far been neglected in Pakistan and needs greater attention in the years to come. The NNS 2011 also provides illustrative data on the increasing need to address nutrition issues of the elderly. And, although not yet evident in the under 5 population, there are intriguing indicators in the NNS 2011 suggesting that Pakistan may be witnessing the double burden of under nutrition and obesity within rural and urban women of reproductive age.

Adult nutrition is marred by a complex interplay factors such as industrialization, urbanization, sedentary life styles, imbalanced diets and shifting socio-cultural norms. These give way to diseases such as hypertension, strokes, coronary heart disease, diabetes and cancers, among others. They tip the nutritional balance in many ways and require a multifaceted approach for interventions ranging from surveillance, research, and social change communication to simply healthy eating habits. The growing group of people over fifty years of age faces nutritional depletions and associated problems that are related to the changing and slowing metabolism of the body and inadequate replenishment of these nutrients. These changes bring along a spectrum of health problems including hypertension; strokes; coronary artery disease;
sarcopenia (loss of muscle mass); glucose intolerance and other metabolic disorders; osteoporosis and bone fractures; and cancers, among others. Efforts should be geared to assimilate and disseminate information on old age health issues and nutrition. Emphasis should also be placed on focusing on this emerging priority area for provision of rehabilitative and consultative services for needy elderly persons.

It is beyond the scope of this report to suggest remedies and discuss nutrition related interventions and strategies in depth. It is envisaged that this NNS 2011 report will provide the basis for further discussion at federal and provincial level for concerted action and strategy development. Pakistan urgently needs a nutrition policy and strategy for a coordinated, interlinked and multi-pronged approach for future endeavours to address malnutrition.
